MENINGOCOCCIC MENINGITIS AND ACUTE MENINGOCOCCEMIA

A CLINICAL STUDY

CHARLES V. CRASTER, M.D., D.P.H.
Health Officer, Department of Health
AND

HENRY SIMON, M.D.
Night City Physician
NEWARK, N. J.

The syndrome produced by the meningococcus organism when it attacks the meninges remains unconquered. One is impressed by its low incidence and high mortality as contrasted with those of other contagious diseases, such as measles and varicella, which have a high incidence and a low mortality. Persons who have not had measles or chickenpox will contract the disease because they have not acquired immunity by having had it. In the case of meningococcic meningitis, only infrequently does one of the many persons exposed to the disease contract it, although about one half of the persons exposed during epidemics become carriers of the organism.

One cannot sit complacently and boast about the tremendous advances in curative and preventive medicine, because the mortality of meningococcic meningitis in the first year of life is still about 50 per cent. In the accompanying table the mortality in Newark, N. J., for the past nineteen years is shown to range from 75 per cent in 1923 to 25 per cent in 1926, 40 per cent in 1932 and 46.8 per cent in 1936. It averaged 44.4 per cent. This figure represents 572 cases, with 254 deaths, including those at all ages. In 1918 there were 102 cases, in 1930 fifty-three, in 1935 eight and in 1936 forty-seven.

Epidemics of meningococcic meningitis tend to appear every ten years in certain localities. This is not true of Newark. A wave of epidemic proportions might strike Newark. It is for this reason that an effort must be made to perfect those measures which will tend to lower the death rate. Our paper has been written with this purpose in mind, namely, to attempt to contribute and to emphasize certain fundamental phenomena, which, when observed at the bedside of the patient, will mean an early diagnosis of meningococcic infection and the early use of effective therapeutic procedures.

Dr. Ellis L. Smith of the Isolation Hospital of Essex County permitted the utilization of case histories and Dr. Harrison S. Martland, chief medical examiner of Essex County, the quotation of autopsy reports. Dr. Josephine B. Neal, chief of the meningitis division of the department of health of New York City, offered valuable suggestions. Dr. Horace Bell, resident at the Essex County Isolation Hospital, verified the diagnosis in cases in which the patient was sent to that hospital. The late Dr. Frank W. Pinneo of the Babies Hospital cooperated in the report of case 3.

There are two theories as to how the meningococcus reaches the meninges. One is that the meninges are invaded by direct extension through the cribriform plate of the ethmoid bone, with the original source of the organism in the nasopharynx. The other is that the organism passes from the nasopharynx into the blood stream and thence to the meninges. Many authorities favor the latter theory. They say that blood cultures are positive before the meninges are invaded and before the spinal fluid becomes cloudy. They add that there are many cases of infection of the blood stream (meningococcemia) without the production of meningitis.

We are going to present some clinical data stressing the rash in meningococcic meningitis. There is a specific rash, just as there is a rash for measles or scarlet fever. However, this rash occurs in only 10 to 15 per cent of the cases. The spots are petechial or purpuric. They occur before the beginning of the meningeal signs, that is, before the spinal fluid becomes cloudy, and disappear by the third or fourth day unless unusually extensive. By the third or fourth day the spinal fluid has in most cases become cloudy. This phenomenon is caused by bacterial emboli in the stage of bacteremia. A massive purpuric rash occurs when the condition is fulminating. The petechiae may be found on any part of the body, most frequently on the extremities. They look like flea bites, hence the term "spotted fever" has been given to this disease. They do not fade on pressure, vary from pinpoint to one-half inch in diameter, often being irregular in shape, and when they fade, leave a rusty stain.

McLean¹ stated that in 83 per cent of his cases he was able to obtain smears showing intracellular meningococci by puncturing a petechial or purpuric lesion with a needle and staining the resultant drop of blood, smeared on a glass slide, with the Gram stain.

Josephine B. Neal² stated that this may be a difficult bacteriologic test and that it may be necessary to wait for the results of the culture of the blood. At times gram-positive organisms are pleomorphic and will decolorize with the Gram stain. Sometimes the meningococcus on an initial smear will not decolorize and appear gram positive. The importance of a smear from a petechial or purpuric lesion is demonstrated by the fact that if gram-negative organisms are obtained a quick diagnosis of meningococcemia may be made, before the blood culture has grown and before any change has taken place in the spinal fluid. A purpuric or petechial rash should, even in the absence of any meningeal sign, enable one to foretell that meningitis

may develop in the near future. Numerous diseases have an accompanying purpuric or petechial rash. A rash due to the presence of the meningococcus requires the finding of that organism. Petechial and purpuric rashes occur when the blood platelets are deficient (thrombocytopenic purpura). Secondary purpura may be due to poisons, such as mercury, arsphenamine and benzene. Infections such as subacute bacterial endocarditis and hemorrhagic forms of the exanthems produce cutaneous

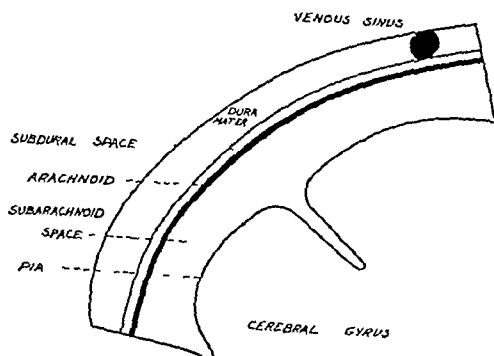

Fig. 1—The meninges (reproduced from figure 257 in Howell W. H. A Textbook of Physiology ed. 9 Philadelphia W. B. Saunders Company, 1927)

hemorrhages. Severe anemia, leukemia or hemophilia may cause purpura. It is therefore obvious that a meningococcemic purpura requires the identification of the etiologic gram-negative diplococcus.

Like the exanthems, certain atypical rashes may occur with cerebrospinal fever. Herrick³ mentioned a maculopapular rash resembling the roseola of enteric fever. Holt⁴ stated that a general erythema or a morbilliform eruption closely resembling measles may be present. Osler described an erythema, dusky mottling and rose-colored hyperemic spots like the typhoid rash.

Boone and Hall⁵ reported a case of fulminating meningococcic septicemia in which a direct blood smear, taken for a routine white cell and differential count, when stained with Wright's stain revealed numerous intracellular and a few extracellular diplococci, the blood culture was positive for meningococci. Thus it is evident that a nonpurpuric skin may harbor meningococci in the cutaneous capillaries, which are demonstrable by obtaining a drop of blood by needle puncture of the skin. This blood is spread on a glass slide and stained with Wright's stain, methylene blue or Gram's stain.

Herrick³ and Burton and Chalmers⁶ emphasized the fact that the presence of a purpuric rash means fulminating meningococcemia. In the case reported by Burton and Chalmers, extensive purpura, associated with hematemesis and melena, was followed by the death of the patient nineteen hours after the onset of illness. A petechial rash means a less fulminating infection than does purpura.

The blood count shows from 15,000 to 60,000 leukocytes, with 90 per cent polymorphonuclears.

Miller⁷ reported a case in a 2 week old child who had giant vesicles filled with cloudy fluid on the

abdomen, upper part of the right thigh and groin. Meningitis developed. Dr. Horace Bell has observed herpetic vesicles on an erythematous base in meningococcic infection. The characteristic location is the lips and the face, but the eruption may be anywhere. It is the most frequent eruption and is common in older children but rare in infants. Tillett and Brown⁸ cited a case in which a confluent herpetic rash on the lips and inside the mouth preceded by several days the appearance of meningeal signs. A smear of fluid from a herpetic lesion may show meningococci. Herpes may appear at any time. The herpes accompanying meningitis must not be confused with herpes zoster. Herpes is rarely seen before the fifth day.

Positive blood cultures have been obtained in from 25 to 30 per cent of cases. If patients are seen early, in the stage of bacteremia, before the spinal fluid becomes cloudy or when the spinal fluid has been cloudy for a short time, a much higher percentage of positive blood cultures will be obtained. This explains the figures given by Herrick,³ who stated that as many as 80 per cent of blood cultures may be positive. This fact is made use of in the therapy at the Essex County Isolation Hospital, where serum is given intraspinally only, and not intravenously, when the spinal fluid is cloudy, because at this stage blood cultures are usually negative.

Certain characteristics of the spinal fluid should be studied when a meningococcic infection is present. The spinal fluid is usually hazy or cloudy. There is an increase in globulin. The sugar is diminished or absent. There is leukocytosis with polynucleosis. The meningococci may be demonstrated with a Gram stain as being either intracellular or extracellular. Very early and very rarely does the physician encounter a case in which he gets a clear spinal fluid. The explanation is obvious. The meningococci have not yet migrated from the blood stream to the spinal fluid. In a case of this kind, if one will wait from twelve to twenty-four hours and repeat the tap, a hazy spinal fluid will be obtained.

Tillett and Brown,⁸ in an analysis of twenty-six cases, mentioned a case in which meningococci were cultured from a spinal fluid which in other respects was normal. It was clear, with 2 cells per cubic millimeter. Serum was given intravenously and the patient recovered.

The meningococcus is the only organism that disappears quickly from the spinal fluid. Often it is difficult to find both by smear and by culture so that a clinical rule has been evolved whereby one is justified in giving antimeningococcus serum in any case in

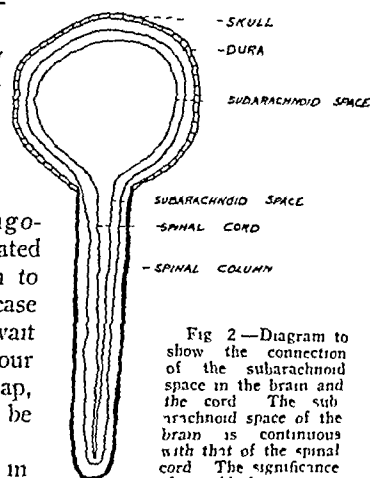

Fig. 2—Diagram to show the connection of the subarachnoid space in the brain and the cord. The subarachnoid space of the brain is continuous with that of the spinal cord. The significance of a block at any given level is shown with the necessity of tapping at a higher level than the block in order to drain the spinal fluid. which the spinal fluid is hazy or cloudy when the etiologic organism cannot be found. The diminution or absence of spinal fluid sugar is characteristic of a meningococcic infection. When the sugar content tends to return to normal the patient is on the road to recovery. One of the earliest signs that a recrudescence or relapse is about to manifest itself is the lowering of the sugar content of the spinal fluid when the patient is apparently well on the road to recovery. Herrick.³

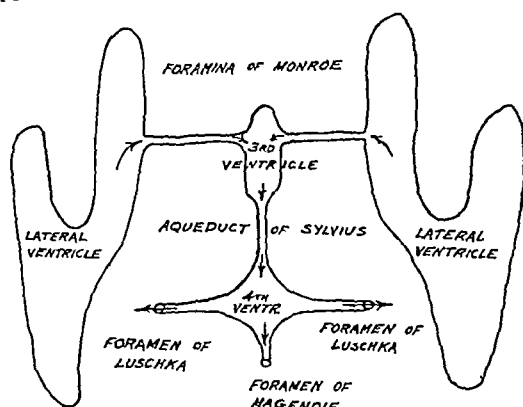

Fig. 3—Circulation of the cerebrospinal fluid. The arrows show the direction of the flow. (Reproduced from figure 260A in Howell, *A Textbook of Physiology*.)

stated that recrudescences and relapses occur in from 20 per cent to 30 per cent of the cases, so it is apparent that the quantitative estimation of spinal fluid sugar as a matter of routine is of definite clinical importance in the prognosis. In conjunction with this lowering of the sugar content of the spinal fluid in a recrudescence and relapse there are a return of the organisms to the spinal fluid and a reappearance of the hazy or cloudy appearance of the fluid.

It is often difficult to obtain fluid by spinal puncture from the new-born or young infant owing to the formation of a block in the narrow foramina or subarachnoid space by inflammatory exudate. The spinal fluid may coagulate in the needle. Cisternal punctures or ventricular punctures should be resorted to.

We are presenting case reports showing (1) the Waterhouse-Friderichsen syndrome, (2) the mental changes in patients with meningococcic meningitis, (3) mono-articular arthritis as the initial phase of cerebrospinal fever and (4) the difficulties encountered by the clinician in the diagnosis of meningococcic meningitis in infancy.

WATERHOUSE-FRIDERICHSEN SYNDROME

The Waterhouse-Friderichsen syndrome is really acute fulminating meningococcemia associated with adrenal hemorrhages. It cannot be distinguished clinically from fulminating meningococcemia, the finding of adrenal hemorrhages on postmortem examination serves as the differential diagnosis between the two conditions.

Four cases occurred in the Aldridge family.

CASE 1—Vivien A, aged 5 years, admitted April 7, 1936 for possible scarlet fever with pharyngitis had as chief complaints sore throat, abdominal pain, aching joints and fever. She did not appear acutely ill. The temperature was 104 F, the pulse rate 134 and the respiratory rate 30. The temperature dropped to 101.8 F the next day but subsequently rose to 104 and reached its peak of 104.8 three days after admission. Thereupon it dropped, and it stayed normal until the patient was dis-

charged April 29. The blood culture was reported positive for meningococci on April 10. The final diagnosis was meningococcic septicemia and acute pharyngitis.

CASE 2—Lawrence A, aged 2½ years, admitted on the same day as his sister, Vivien, appeared normal. The temperature, pulse and respirations were normal. There were no physical abnormalities. For three days the child's condition remained unchanged. On April 11 the temperature shot to 104.8 F. The patient looked toxic but the lungs were clear and there were no neurologic signs. Petechiae were seen over the elbow and the abdomen. A blood culture was positive for meningococci. Fourteen cubic centimeters of antimeningococcus serum was administered intravenously, but the child went into shock in spite of a negative sensitivity test. The next day petechiae appeared over the entire body and in the bulbar portion of the conjunctiva of the right eye. No Brudzinski sign or contralateral reflex was elicited, but there were questionable stiff neck and a questionable bilateral Kernig sign. Spinal tap showed a cloudy fluid (12,700 cells, with 97 per cent polymorphonuclears). Serum was given intraspinally. After a stormy course the child recovered, and he was discharged on May 9, after being at the hospital one month.

CASE 3—Bernard A, aged 1½ years, was admitted April 9, 1936, moribund, stuporous and cyanotic, with a temperature of 105 F. The parents did not notice that the child was sick until 3 a.m. the night before admission, when he appeared to have a fever.

Neurologic examination gave negative results except that it showed slight rigidity of the neck, a slight Kernig sign and no rash. The hemoglobin content was 59 per cent and a blood count revealed 4,200,000 red cells and 14,250 white cells with 54 per cent lymphocytes.

The patient died on the day of admission. Autopsy showed the classic appearances of the Waterhouse-Friderichsen syndrome.

The brain was characterized by acute encephalitis with pia-arachnoid edema. It was moderately wet, the gray matter throughout the cortex and the basal nuclei was pinkish and there was no meningeal exudate over the top of the brain. The pons, medulla, fourth ventricle and cerebellum were soft and pink, with no gross exudate. Meningococci were cultured from material obtained from the pia-arachnoid by inserting a swab made from a sterile platinum loop. Both adrenal glands showed medullary and cortical hemorrhages. Other pathologic changes were cloudy swelling of the liver, kidneys and heart and hyperplasia of the thymus.

McLean and Caffey¹ and other investigators have demonstrated that children having an enlarged thymus and a "status thymicolymphaticus constitution" are least resistant to the meningococcus organism.

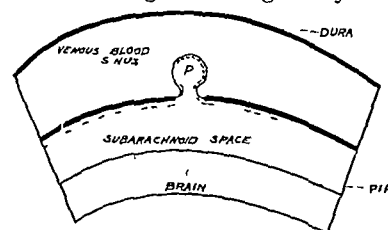

Fig. 4—Pacchionian bodies (arachnoid granulations). Since the subarachnoid space is a closed cavity filled with the cerebrospinal fluid which is secreted by the choroid plexus, some means of egress must be furnished for the fluid. This exit is provided by a system of filters called the Pacchionian bodies (P). (Reproduced from figure 260 in Howell, *A Textbook of Physiology*.)

CASE 4—Richard A, aged 3½ years, had a short history of illness and died at home. The postmortem appearances were the same as those of his brother Bernard (case 3).

Dr. Martindale accepted in these cases a diagnosis of fulminating meningococcic meningitis with bilateral adrenal hemorrhages. It must be remembered that there is no gross exudate in the meninges. The infection is so fulminating that often the child dies in the septicemic stage with a clear spinal fluid and no meningeal signs.

CASE 5—A woman aged 42, was admitted in a comatose state and died shortly afterward.

Autopsy showed petechiae in the brain but no gross exudate of meningitis. Petechiae were present in the kidneys, intestine and heart, there was no endocarditis. Petechiae and hemorrhages were seen in both adrenal glands. The lungs showed no pneumonia. Meningococci were obtained from the pia-arachnoid by inserting a sterile platinum loop, thus establishing the diagnosis of the Waterhouse syndrome, which requires the finding of meningococci, hemorrhages in the adrenals and a fulminating infection, with death often occurring before a purulent meningeal exudate develops.

In some cases of this syndrome the resistance of the patient is strong enough to ward off death, permitting the invasion of the meninges, with the formation of a definite purulent meningeal exudate and cloudy fluid. An autopsy must be performed in these cases to establish the presence of adrenal hemorrhages. McLean and Caffey¹ said that the cause of early death is adrenal hemorrhage, which produces a clinical picture of marked prostration with intense cyanosis and shock.

In one of Aegerter's² patients, a 7 year old boy, the following pathologic changes were observed post mortem. Petechiae were present in the mucosa of the mouth, larynx, stomach, intestine and skin and hemorrhages from 1 to 3 mm in diameter throughout the peritoneum, pleura and pericardium, the adrenals were almost as large as the kidneys and were purple, the capsules were tense with blood, the brain was wet and heavy but showed no overt meningitis. Death had occurred nineteen hours after the initial symptom.

Only fifty-six cases had been reported in the literature up to May 1936. Examination of the spinal fluid gave relatively negative results, in only six cases did it demonstrate the presence of meningitis. The absence of a cloudiness of the spinal fluid was due to the fulminating nature of the disease and the quick death of the patient, who died before purulent meningitis occurred.

Treatment of the Waterhouse syndrome depends on early diagnosis with immediate intravenous use of meningococcus serum. The presence of adrenal hemorrhages and depletion of the sodium ion in the blood, with symptoms of adrenal failure (hypotension, weakness, low blood sugar content and circulatory collapse), suggest that adrenal cortex extract, dextrose given intravenously, epinephrine, fluids (saline solution given by vein) and transfusions be used.

THE CHANGE IN MENTALITY IN MENINGOCOCCIC MENINGITIS

CASE 6—David W., a Negro, aged 40, was drowsy, fell asleep when not disturbed, did not answer any questions put to him, resisted any attempt to examine him and refused to open his mouth. We had to have a man hold his head and another hold his hands so that we could pry his jaws apart to look into his mouth. He preferred to lie on his side with his legs drawn up. No matter how we shouted at him he refused to answer or cooperate. He was too weak to sit by himself. He had a boardlike rigidity of the neck. Bilateral Kernig and Brudzinski signs were elicited. His knee jerks were hyperactive. He resisted having his temperature taken. His pulse rate was 120 and his blood pressure 130 systolic and 70 diastolic. He resisted our looking at his pupils refusing to open his eyelids. His abdomen was soft. Spinal tap showed cloudy fluid with a cell count of 7,200, polymorphonuclears 60 per cent globulin 4 plus and the sugar content diminished. Examination of a smear gave negative results, but culture showed meningococci.

This case illustrated well the loss of mentality, the septic adult brain became the brain of a 2 year old child who would not answer questions and resisted examination. Herrick³ stated

The patient is dull, apathetic, indifferent, he plaintively resents disturbance, responds in monosyllables with the expenditure of a minimum amount of energy, and prefers to lie on the side with knees drawn up and head bent forward. There is no modulation of voice or play of expression. Silence and immobility are striven for and active delirium or coma are infrequent. This striking deviation from the normal mentality at once arrests the attention of the experienced observer.

A 2 year old child with meningitis showed the mental state and hyperesthesia. She had marked rigidity of the neck, screamed in pain when handled or moved and when the stiffness of her neck was demonstrated. She remained quiet and asleep if not disturbed.

In Tillett and Brown's⁴ series, almost all the twenty-six patients presented acute alterations in the mental faculties. The delirium present in fourteen either was short and transient or consisted of prolonged periods of violent purposeless activity. Generalized hyperesthesia was present in most of the patients. Hyperesthesia is present when there is a painful response to physical examination and nursing care. It produces excessive crying, resistance to examination and exaggerated reflexes and may be so intense that any movement of the body causes agonizing cries. The patient is greatly disturbed and cries lustily on hearing a loud noise or being exposed to a bright light. Ravid¹⁰ described the crying as being incessant and brought about by the slightest touch, as though pain was evoked. The peculiar, intense, high pitched cry has been termed "the hydrocephalic cry of increased intracranial pressure."

Occasionally, as illustrated by Holt and McIntosh,⁵ there is at the beginning of meningococcic meningitis no loss of mentality whatever, the patient being mentally alert, as was demonstrated by the following case, which we observed at the Newark Salvation Army quarters.

CASE 7—Joseph D., aged 48, admitted with pain in the back of the neck and frontal headache of two days duration, had done no vomiting but was anorexic. The physical examination showed that he was mentally alert. He had a temperature of 102 F, his neck was very stiff, and bilateral Kernig and Brudzinski signs were elicited. The spinal fluid was cloudy, with 8,000 cells per cubic millimeter. This man was not disturbed mentally by the presence of meningitis. He was not drowsy, as was David W., who showed extreme drowsiness, but he also died.

CASE 8—Daniel R., a Negro, aged 31, a chicken plucker by occupation had a history of chills and fever initiating the onset of illness. He was irrational and uncooperative and kept talking about plucking chickens. He reassembled and pecked at the bedclothes as though he were removing feathers from chickens maintaining an intermittent delirious chatter. The neck was very stiff. The pupils were dilated and did not react to light. The patient resisted examination and the mouth could not be opened. A spinal tap showed the presence of meningococci meningitis. The patient died.

CASE 9—Raymond B., a Negro, aged 17 was delirious. He screamed loudly, was extremely excitable and kept repeating the words "mama pip one two." He was irrational showed marked carphologia and resisted examination. There was boardlike rigidity of the neck and spinal tap showed the cloudy fluid of meningococcic meningitis. The patient recovered.

⁹ Aegerter E. E. Waterhouse Friderichsen Syndrome. Review of the Literature and Report of Two Cases. J. A. M. A. 106: 1715-1719 (May 16) 1936.

¹⁰ Ravid J. M. Meningococcic and Nonmeningococcic Meningitis in New Born and in Young Infants. Am. J. Dis. Child. 49: 128-129 (May 1932).

In conclusion, we may state that the foregoing case reports illustrate extreme drowsiness, delirium producing an irrelevant chatter, resistance to examination, inability to answer questions and hyperesthesia

MONO-ARTICULAR ARTHRITIS AS THE INITIAL MANIFESTATION OF MENINGOCOCCIC MENINGITIS

CASE 10—Jeanette P., aged 6 years, was admitted with a history of two days of pain in the right elbow. The tentative diagnosis was rheumatic arthritis of the right elbow or "observation meningitis." On the second day the temperature was 105 F. The patient was drowsy, complaining of headache, and had slight resistance of the neck but no real rigidity. Petechiae appeared. On the third day there were definite stiff neck and Kernig and Brudzinski signs. Spinal tap showed the cloudy fluid of meningococcic meningitis.

This case clearly shows some of the difficulties the clinician may experience in making an early diagnosis of meningitis. During the first two days of illness the child had a mono-articular involvement of the right elbow, with a fever and no neurologic signs pointing definitely to meningitis. When the petechiae appeared, on the second day, meningococcic bacteremia was suspected.

Carnot¹¹ mentioned a triad of manifestations of meningococcemia consisting of "intermittent fever, arthralgia, and a hemorrhagic eruption."

CASE 11—Robert H., a Negro, aged 5 years, was admitted with pain and tenderness in the right knee. The knee was so tender that it could not be touched, but it did not appear swollen, he cried when it was moved. A tentative diagnosis of rheumatic arthritis of the right knee was made. The temperature was 101 F. on the first day of illness. The next day severe headache and nonprojectile vomiting developed, but the right knee was not as tender as before. On the third day the child kept his head turned to the right and had classic meningeal signs. The temperature was 103 F. A spinal tap showed cloudy fluid with a cell count of 5,680 and 90 per cent polymorphonuclears, globulin 3 plus and sugar absent. A smear of spinal fluid showed meningococci. The patient recovered.

This boy had no meningeal signs the first two days of his illness, which means that one must be suspicious of meningitis when an illness is initiated by tenderness and pain in one joint followed by headache and vomiting.

Tillett and Brown described the syndrome of polyarthritides that occurred in nine of their twenty-six patients. The joints showed pain, swelling and signs of fluid. In six cases a joint was tapped and the fluid was thick, cloudy and rich in polymorphonuclears, in three cases meningococci were cultured from the fluid. Herrick³ mentioned that acute arthralgia or polyarthritides is often an initial symptom and that an erroneous diagnosis of purpura rheumatica (Schonlein's purpura) may be made, owing to the combination of joint pain, tenderness and purpuric spots with no obvious meningeal signs. Indefinite pain in the joints, particularly in the knees, may mean meningococcemia, with meningitis developing from two to four weeks later. The knees are involved most frequently and the wrists next. Applebaum stated that chronic meningococcic septicemia may start with arthritic symptoms. In some cases the arthritis is present at the onset of the disease, while more frequently it appears as the meningitis is beginning to subside. There may be pain in the joints without any external evidence of inflam-

mation. Joints, the seat of meningococcic arthritis, usually completely recover, with no permanent disability.

MENINGITIS IN INFANCY

The following cases illustrate diagnostic criteria for meningitis in infancy.

CASE 12—A boy, aged 3 months, had a peculiar cry, nystagmus and bulging fontanel. The neck was not rigid and the Kernig sign was not elicited. There was a Brudzinski sign. The temperature was 104 F. Spinal tap yielded cloudy fluid from which meningococci were isolated.

The absence of rigidity of the neck and of Kernig's sign are characteristic of meningococcic meningitis at this age.

CASE 13—John Mc., aged 4 months, admitted with a temperature of 104 F. and a purpuric and petechial rash over the legs, abdomen and chest, was drowsy and his eyes showed nystagmus with widely dilated pupils. The fontanel was not bulging. The neck was not rigid, and Kernig and Brudzinski signs were not elicited. A spinal tap showed 2,300 cells per cubic millimeter, most of which were polymorphonuclears, and a smear showed meningococci. The child died within twelve hours after the onset of symptoms. The condition was fulminating meningococcic meningitis.

DIAGNOSTIC CRITERIA FOR INFANTS AND FOR ADULTS

Josephine B. Neal¹² stated that in many infants meningitis starts as gastro-enteritis with vomiting, slimy green stools and a fever and with or without bulging of the fontanel, and that there are no signs of involvement of the central nervous system, such as Kernig's sign or stiff neck, early in the disease. The doctor who is not aware of this syndrome will treat the condition as gastro-enteritis, and the diagnosis will be made after ten days or two weeks of the disease, when the stiff neck and Kernig sign appear. By this time the disease is far advanced. It should be remembered that meningitis may be present in the first and second years of life when bulging of the fontanel is associated with an irregular fever higher than one would expect from gastro-enteritis and when gastro-enteritis is not responding to the ordinary methods of treatment. Ravid¹⁰ has reported a series of cases in infants in which constipation, vomiting and abdominal pain marked the onset of a meningococcic infection and so obscured the clinical picture that an initial diagnosis of an acute condition within the abdomen, such as intussusception or pyloric stenosis, was made. Abdominal cramps were prominent. There may be bloody stools in cases of the gastro-enteritis accompanying a meningococcic infection, but this symptom is rare. The vomiting is usually nonprojectile, being in infants a regurgitation.

It must be noted that an infection of the upper respiratory tract often precedes meningitis in infancy and that "grip" or an "influenzal" infection at times precedes the meningeal signs in adults. Josephine B. Neal expressed the opinion that this infection or influenza is caused not by the meningococcus but by other organisms, which reduce the resistance of the patient to such an extent that the body succumbs to a superimposed meningococcic infection.

The bulging of the fontanel is a very important sign. It is usually termed a "lump on the head" by the mother. It is an indication that the ventricles are distended with spinal fluid. The examiner should put

¹¹ Carnot Paul. *Rev. gen. de clin. et de therap.* 46: 97 (Feb. 13) 1932.

¹² Neal Josephine B. *Experience of the Meningitis Division of New York Department of Health.* *Am. J. Pub. Health* 21: 147-162, 1931.

the infant in a sitting position to determine whether the fontanel bulges, as when the child is supine the state of the fontanel may be deceiving.

The absence of bulging of the fontanel does not rule out meningitis, as the cranial sutures in infancy are elastic. The increased intracranial pressure may merely serve to separate the cranial bones, without producing a bulging of the fontanel. When the child cries he tends to produce the condition.

If the baby has a petechial rash or a swelling of a joint, one must rule out a meningococcic invasion of the blood stream. The presence of herpes with a fever of obscure origin may mean meningococcemia.

Fretfulness, refusal to nurse or restlessness may herald meningitis. The bright child loses his vivacity. He may be irritable at all times or only when disturbed for examination or feeding. He may be stuporous and difficult to arouse but when he is aroused may manifest irritability.

The patient suffers from acute pain and may complain of generalized soreness. The pain is usually situated in the frontal and occipital regions of the head.

*Statistics on Meningococcic Meningitis in Newark, N. J.**

* Two striking phenomena about an epidemic are the low morbidity and the high mortality as contrasted with those for other contagious diseases.

but may involve also the lower extremities, back or abdomen. It varies in severity throughout the day, being worse at night. When one attempts to flex the neck, an intense cry due to pain in the occipital region is elicited.

The presence of exaggerated tendon reflexes in a quiet or somnolent patient who is acutely ill or febrile may mean meningitis. Normal infants, excited by the manipulation of examiners and strangers, often show hyperactive reflexes, so these signs must be used in conjunction with other objective phenomena pointing to a cerebral irritation. The deep reflexes may be normal, diminished or exaggerated, no uniform variability being present. The superficial reflexes are of no value. Fever, hyperesthesia and increased reflexes may be the only early signs.

The Kernig sign is very important in the diagnosis of meningitis in adults. It is found in a considerable number of normal infants and may not occur in infants who have cerebrospinal fever. Its absence should not lead one to exclude meningitis, its presence should make one look for other signs.

The Brudzinski sign is important in adults, but it is found in many normal infants. Its presence does not have any significance unless associated with other signs of meningitis.

Tonic spasm of various muscular groups is a constant sign, which, although it does not occur early, is always present during the course of meningitis. Tonic muscle spasm gives rise to the stiff neck, Kernig's sign, Brudzinski sign and cervical and general opisthotonos. Tonic spasm of the upper and lower extremities causes flexion of the arms, legs and thighs, to which the term "gun hammer" has been applied. The extremities may be held in extension. Stiffness of the neck may, as shown by Eagleton, be intermittent. Risus sardonius and trismus have been reported.

A Babinski sign is present normally during infancy and is not characteristic of meningitis. Ravid¹⁹ said that distention of the veins of the neck is a valuable sign. The tache cerebrale is very marked, as in all forms of meningitis.

The onset of a meningococcic infection is usually attended by a moderate or high fever, with a normal or slightly increased respiratory rate. The temperature curve is irregular, the fever having periods of remission or exacerbation. In a remission, the temperature falls to normal, or nearly normal and remains there for several days. When the patient is seen in this period the condition may be difficult to diagnose. Afebrile period may occur at the beginning of a meningococcic infection and further contribute toward hiding the presence of a febrile illness, fortunately, this occurrence is rare. Some patients never show much fever. According to Herrick,³ prolongation of fever beyond the seventh day suggests that treatment is inefficient. At that time complications and serum sickness are additional causes for prolongation of the fever. There is nothing characteristic about the relationship between the pulse rate and the temperature. The pulse is usually more rapid than normal, and it is subject to sudden changes in rate, as the intracranial pressure rises a relatively slow rate may appear, and if there is general debility the pulse will be rapid. One does not see the rapid respirations that a patient with pneumonia has. The combination of rapid respirations and meningeal signs usually means pneumonia with meningismus.

Macewen's sign is of no value except when there is distention of one ventricle, when a slightly tympanic cracked-pot percussion note is elicited over the distended ventricle. This sign is rarely used.

A convulsion in a baby may mean meningitis. It is of no special diagnostic significance, since any febrile disturbance in infancy may produce a convulsion. Instead of a generalized convulsion, localized intermittent tremors and twitchings of an extremity or of one side of the face may occur. The picture may be identical with that of tetany or intracranial hemorrhage in the infant. The combination of convulsions, a hemorrhagic eruption and cyanosis may mean fulminating meningococcemia.

Careful observation of the eyes of a febrile infant may enable one to detect meningitis. One should watch for nystagmus, which occurs early. Nystagmus may occur only on attempted flexion of the head. The ocular movements may be slower than in true nystagmus and involve one eyeball only. If both eyeballs are involved, their movements show dissociation. Strabismus may be present. At times there is ptosis. Retraction of the upper eyelids may be noted. The pupils are

usually contracted early in the disease. Later they may be fixed, dilated or unequal and not respond to the light reflex. The child may appear sightless and have a peculiar stare. Hippus may be present. Ravid¹⁰ stated that purulent conjunctivitis may be the first sign to usher in the disease, but it is usually diagnosed as being of gonorrheal origin, the true aspect manifesting itself only several days afterward. Choked disk may be present, but it is not a frequent or a constant symptom. The papilledema, when it does develop, is due to an internal hydrocephalus. Choking of the disk is therefore a complication and not an early sign in meningitis. The eyegrounds are normal early in the disease and are of no aid in making an early diagnosis.

There is no evidence early in this syndrome of any weakness of the extremities, such as occurs in poliomyelitis. Partial or complete paralysis of an extremity constitutes a complication and occurs late in the course of cerebrospinal fever.

SUMMARY

A thorough knowledge of the bacteriology, anatomy and physiology of the meninges and the cerebrospinal fluid is essential for the proper early diagnosis and treatment of meningococcic infections.

Meningococcic infections have a low incidence and a high mortality. In the city of Newark during the past nineteen years there were 572 cases, with a mortality of 44.4 per cent.

A petechial or purpuric rash may be considered the specific rash of meningococcemia. A purpuric rash accompanies the petechial rash when the condition is fulminating. The rash occurs before the spinal fluid becomes cloudy and before the onset of meningeal signs and persists after definite meningeal signs appear. In many cases meningococci can be demonstrated by a Gram stain of blood obtained by needle puncture of a petechial or purpuric area. A Wright stain of blood from a nonpurpuric skin may also demonstrate meningococci.

Acute fulminating meningococcemia associated with adrenal hemorrhages has been termed the Waterhouse-Friderichsen syndrome.

A meningococcic infection attacked four children in one family, with recovery of two and death of the other two, and postmortem examination revealed the typical pathologic changes in the Waterhouse-Friderichsen syndrome. Cases 3 and 4 of this group illustrate the quick death of the patient, within twenty-four to thirty-six hours after the onset of symptoms. Negative tests of the spinal fluid have been reported in a majority of similar cases.

Three of the cases reported illustrate toxic encephalitis secondary to meningococcic meningitis, in such cases striking deviations from the normal mentality attract the attention of the experienced observer.

Two patients had initial complaints of pain and tenderness in one joint, necessitating a tentative diagnosis of mono-articular arthritis. The stiff neck and Kernig sign did not appear until two days after the onset of arthritic symptoms.

In infancy, particularly in the first and second years of life, the early signs of meningococcic infection of the meninges do not point to involvement of the central nervous system. They are more likely to suggest an infection of the upper respiratory tract or a gastrointestinal disturbance. After the disease is well established, the stiff neck, the Kernig and Brudzinski signs and other meningeal signs appear.

VASCULAR ACCIDENTS OF THE EXTREMITIES

GÉZA DE TAKÁTS, M.D.

CHICAGO

The term vascular accident has not been used in relation to the extremities. It implies, however, that a sudden unexpected change takes place in circulation in the form of hemorrhage, embolism or thrombosis. It also means that emergency measures have to be adopted, the promptness of which may save the limb or the life of the patient. In this brief discussion I plan to outline the types of vascular accidents which occur in the arterial and venous system of the extremities, together with their immediate and delayed treatment.

The general practitioner knows of the accident first in the overwhelming percentage of cases, early recognition and early simple measures may be deciding factors in the ultimate outcome of the emergency.

ARTERIAL HEMORRHAGE

A clean division of an artery, as contrasted with a blunt crushing injury, is more apt to lead to hemorrhage, since arterial contraction is less effective and blood-clotting substances less abundant in the clean cuts of the arterial wall.¹ Gunshot wounds, stab wounds or fragments of fractured bone are the most frequent causes of massive arterial hemorrhage. If the hemorrhage is external, pouring through a break in the skin, digital compression or constriction above the injury will have to stop the bleeding. However, if bleeding takes place in the soft tissues, with formation of a large hematoma, such bleeding can arrest itself when the pressure of the extravasated blood becomes equal to the pressure within the artery. Such a hemorrhage will frequently result in the occlusion of the vessel except when an aneurysm or a so-called pulsating hematoma develops.^{1a}

Severe trauma to large vessels, then, may result in hemorrhage, thrombosis or aneurysm, but in any case the signs and symptoms of vascular impairment must be looked for. Subjectively, numbness, tingling and pain in the bloodless area are the complaints. Motor paralysis is sometimes the first symptom. Objectively, pallor, cyanosis, a drop in the temperature of the skin and loss of pulsation are observed. If nothing is done or nothing can be done to relieve the vascular occlusion, gangrene develops in a certain percentage of cases. An important condition often unrecognized frequently occurs after trauma in the neighborhood of a vessel. A traumatic vessel spasm may so contract a contused artery that it closes completely and organic closure is simulated.² The spasm is occasionally indistinguishable from an actual closure of the vessel, and, even if the vessel is closed by a clot, a certain amount of spasm is always present in the collaterals. This is important, as it necessitates special measures to overcome this part of the vascular accident.

Obviously, bleeding must be stopped. Bleeding from a middle-sized or large artery cannot be stopped by

packing Temporary constriction, which should not last longer than from one-half hour to an hour, must be followed by ligation or suture. Ligation of a larger artery must be undertaken with the understanding that, dependent on the site, gangrene follows in a certain percentage of cases. In figure 1 the underlined numbers represent the percentage of gangrene following ligation of the artery at the site indicated, based on the collective statistics of Heidrich. It will be noted that ligation on the upper extremity is much less dangerous and that the risk of gangrene for ligation on the lower extremity is 100 per cent for the aortic and for the common iliac artery, 13 per cent for the external iliac artery, 21 per cent for the common femoral artery, 37 per cent for the popliteal artery and none for the posterior tibial artery.

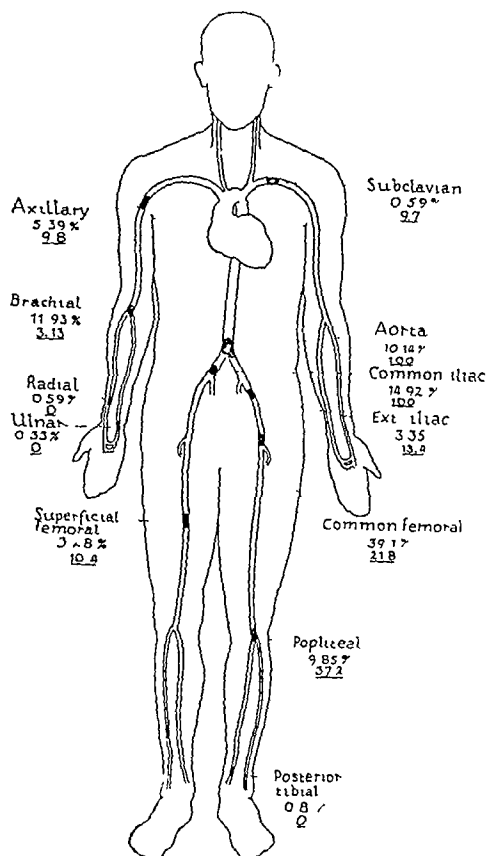

Fig. 1.—Diagram of peripheral arterial occlusions at typical sites. The first figure indicates the incidence of emboli calculated from the collective statistics of Pearse.⁴ The figure below it, underlined, represents the percentage of gangrene following ligation of the artery based on the collective review of Heidrich (cited by de Takáts⁵). Obviously, an embolus produces far more embarrassment of circulation than a simple aseptic ligation. However, the underlined figures give a fair idea concerning the danger that gangrene will follow at a given site.

These are of course only average figures, but they give a fair indication of the risk of tying a large artery. To minimize the erosion of the vessel wall by the ligature or by accompanying infection, the vessel should be doubly ligated and severed. The stumps are then transfixed with a suture ligature, to ensure against slipping. If the distal stump shows pulsation, collateral circulation is abundant. If not, it is wise to tie the concomitant vein, as the increased venous pressure aids circulation temporarily and may tide the limb over the critical period.³ An extremity whose large artery

is ligated needs further care, even if it does not become gangrenous. It is cold, numb and pulseless, the muscles become atrophic, contractures of muscles and tendons may develop, and ischemic neuritis sets in. As soon as the injury is healed all measures known to increase collateral circulation must be employed. These will be discussed later, together with the general therapy of arterial occlusions.

When equipment and previous training enable the surgeon to attempt a suture of the artery, the suture will yield far superior results than ligation. Nobody can have enough opportunity in civilian practice to perfect himself in the technique of arterial sutures, but I would suggest to the younger men that they study it on the experimental animal. Suitable needles and suture material can be kept on hand in ampules. The technique of arterial sutures can be learned by any one who can undertake to suture an injured or perforated bowel, and yet sutures are not done as often as they should be.

ARTERIAL EMBOLISM

When an artery of the extremity is suddenly occluded by a clot which has been thrown off from the heart or from a vessel proximal to the obstruction one speaks of an arterial embolus. The sources of such emboli are shown in table 1. The main source of the left side of the heart, the mitral stenosis following coronary thrombosis are the two most frequent types of heart disease which are complicated by peripheral embolism. Rarely, a thrombus may break loose from the field of operation and produce an embolus toward the periphery. Figure 1 shows the incidence of embolus at various segments of the arterial tree. The symptoms of sudden arterial occlusion are variable and multiple. The classic description is that of a sudden excruciating pain at the site of the embolus in a patient suffering from heart disease, simultaneously the affected extremity becomes paralyzed, cold and pale, and the pulses disappear. Within a few days the skin becomes mottled, then diffusely cyanotic or gangrenous.

According to my experience pain is not always a prominent symptom, at least not at first, numbness and tingling or motor paralysis may precede the pain by several hours. Furthermore the pain is not due to an impact of the clot against the vessel wall, but, as Sir Thomas Lewis⁴ pointed out, is due to ischemia of the musculature. In some of my cases pain has been entirely absent.

Arterial thrombosis, in contrast, usually comes on gradually. There is often some preexisting evidence of peripheral arterial lesions such as arteriosclerosis or Buerger's disease, and there is no obvious source of embolism in the heart. Yet it must be emphasized that the differential diagnosis between arterial embolism and thrombosis is sometimes difficult and occasionally impossible.⁵ Thus, it has been noticed by several observers that arterial embolism is sometimes not as sudden as the textbooks would have it and that numbness, coldness and tingling may appear days and weeks before the fulminating symptoms. The former are probably due to preliminary showers of the central clot, which is about to break loose. On the other hand arterial thrombosis, which usually has a gradual onset may occur so suddenly that it is the first recognized

symptom of a widespread arterial disease. One sees occasionally popliteal thrombosis in an elderly arteriosclerotic patient or in a juvenile thrombo-angitic patient which may be mistaken for embolism. The differential diagnosis between arterial embolism and thrombosis has more than academic interest.

In spite of all that has been said recently of various conservative measures to increase circulation when an embolus occludes an artery, the extraction of the clot

is still the optimal method of treatment. In order to define the indications for an embolectomy, it is well to examine the factors which determine the ultimate fate of a limb affected by acute arterial occlusion. They may be readily grouped under four headings: (1) the condition of the heart, (2) the condition of the vessel wall at the site of obstruction, (3) the condition of the collateral vascular bed and (4) the time elapsed between the early symptoms and effective treatment. Of these four factors, the condition of the heart and of the vessel wall cannot be influenced. There is in fact a danger of aggravating circulation by overanxious digitalization. I have repeatedly learned from our medical staff at St. Luke's Hospital that patients who are indiscriminately digitalized after coronary occlusion are more apt to throw peripheral emboli. Digitalis in the treatment of coronary occlusion is indicated only in the presence of decompensation; it slightly constricts the coronaries and increases muscular contractions. The last two patients with multiple embolism whom I saw were both heavily digitalized after coronary thrombosis.

One can, however, influence the time factor and the state of the collateral vascular bed. In regard to the time factor, the statistics of the Swedish surgeons provide a model example. Key's collective review shows that the medical profession in Sweden has become conscious of the utmost urgency of the situation. Of 213 embolectomies, 135, that is, 63 per cent, were performed within the first ten hours.⁶ What that means in regard to results is shown in table 2.⁷ In this country Herrmann's⁸ latest figures show that of twenty-one patients with acute embolism ten could be treated within the first twelve hours and that of twenty-five patients with thrombosis six, or 30 per cent, were referred for treatment within twelve hours. My material, consisting of a total of fifty patients suffering from sudden arterial occlusion, contains fifteen patients who had arterial embolism, in only five of these could exploration be done, and only two arrived within less than ten hours. It seems that those of us who teach surgery in medical schools have not done our duty to

impress the medical profession with the utmost urgency of acute arterial occlusion. The general attitude is that the leg will become gangrenous and the patient will die anyway.

It might be well to state what can be accomplished when the patient is seen in the first ten hours. First one must make an attempt to differentiate between embolism and thrombosis, keeping in mind the possibility of venous thrombosis with arterial spasm, which will be discussed a little later. Then one must try to localize the site of occlusion and determine, on the basis of the patient's age, cardiovascular status and the available collateral bed, whether or not gangrene is to be expected. Gangrene seldom follows an embolus to the upper extremity, and while embolectomies on the upper extremity are uniformly successful, they are unnecessary, for one can get along without them.

Thirdly, intensive conservative measures must be adopted to open up the entire collateral bed and produce as much peripheral vasodilatation as possible. These measures are available to every practitioner, and I have seen limbs saved by a systematic use of peripheral vasodilators. A large heat cradle must be placed over both lower extremities and the abdomen,⁹ it can be improvised in any home. The temperature in the cradle need not exceed 90 F. The use of excessive heat to the extremity is harmful, as heat creates an increased demand for oxygen, and that accentuates the arterial deficiency. The limb should not be elevated, as it commonly is, because elevation only decreases arterial inflow, on the contrary, it should be in a dependent position, somewhere between 10 and 15 degrees below the horizontal position. The angle must be so selected that the tips of the extremity regain their normal color.¹⁰ They should be neither pale from too much elevation nor dusky red from too much dependence. Next an intravenous injection of a potent vasodilator is given. Papaverine hydrochloride in one-half gram (0.03 Gm.) doses¹¹ or sodium nitrite in 1 gram (0.06 Gm.) doses is kept on hand, dissolved in a few cubic centimeters of physiologic solution of

TABLE 2—Results of Embolectomy (Pearse⁷)

| | Percentage Successful * |
|--|-------------------------|
| First ten hours | 40 |
| Second ten hours | 14 |
| Third ten hours | 8 |
| No successful operations after forty eight hours | |

* Success is defined as restoration of circulation for at least one month.

sodium chloride or distilled water and boiled in a spoon over a flame just before use. These doses have been so selected that, while the general blood pressure is affected little or not at all,¹² an enlargement of the vascular bed, chiefly the venocapillary part, takes place. This aids circulation and overcomes the initial vasoconstriction, which accompanies all acute vascular occlusions. Obviously the heat and the vasodilators are not going to influence the clot, but they do open up the collateral arterial pathways, which, curiously enough, are in a state of spasm. This spasm is due

partly to fear, pain or shock, following the embolism, but is specially pronounced in the affected extremity as a reflectoric vessel spasm.⁵

When a negative and positive pressure apparatus is available, it also can be applied to the affected extremity. According to my experience, however, these machines are far more helpful at a later stage, when a slow and gradual enlargement of the collateral vascular bed is desirable. In the treatment of acute obstruction, their use has specially been urged by Herrmann,⁸ but he said that they act in overcoming the vessel spasm, which may easily be overcome by heat and drugs. Intermittent venous hyperemia has also been found to be useful in the treatment of the late sequelae of acute occlusions.¹²

In a large number of cases, the aforementioned simple measures suffice and the limb regains its normal color and temperature. If this does not happen within an hour after the administration of vasodilators, the limb is headed slowly or rapidly toward gangrene. In communities where the physicians are awake to the great seriousness and urgency of this vascular accident, early treatment may save a number of lives and limbs.

In the small group of cases in which early conservative measures have not brought about an improvement in circulation but in which, on the other hand, the limb is not yet ready for amputation, embolectomy should be attempted. That the results are poor after the first ten hours has already been stated, yet one may save a limb occasionally after twenty-four hours. The reason for the great hurry in removing the clot is not only that muscle and nerve tissue, deprived of arterial blood, will suffer permanent damage but that the obstructing clot continues to grow, chiefly in the form of a descending thrombus, which plugs up collateral vessels and defies the purpose of the late embolectomy. In addition the vessel wall starts a reactive process against the clot and becomes irritated, and when such a vessel wall is sutured thrombosis readily occurs at the suture line.

The embolectomy itself is not difficult when suitable equipment and team work are present. Most frequently the groin and the popliteal fossa are explored with the patient under local anesthesia. Nystrom¹⁴ has shown that clots in the aorta or the common iliac artery may be approached from an incision at the groin and with subperitoneal massage can be brought out through an incision in the femoral artery.

Embolectomy is futile after forty-eight hours or even before that when there is manifest gangrene or when the underlying disease is apt to be fatal within a short time, as are septic endocarditis and terminal cardiac decompensation. It is seldom indicated in the upper extremity.

Recently the impression has gained ground that early conservative measures will make embolectomies unnecessary. The answer to this problem can be found by examining the fate of limbs after embolectomy and after conservative measures. About one half of the patients who have a successful embolectomy within the first ten hours and do not die of the underlying cardiac disease leave the hospital with restored circulation. Strombeck,¹⁵ who published some late results, found that, of such patients, three fourths were alive after one year, half after three years, one

third after five years and one eighth after ten years. These are encouraging figures when one realizes how severely handicapped these patients are. Much less is known about the circulation of the extremity that has survived the acute vascular occlusion without gangrene and without embolectomy. I have under observation five patients with such an extremity. In each case it is pulseless and atrophic, the muscles contracted and fibrosed and the skin scaly and mottled. The leg is very painful because of ischemic neuritis, and severe intermittent claudication is present. If there is a demonstrable vessel spasm, the fibrosed artery may be excised or lumbar sympathectomy done to break up the reflex vasoconstriction. While the limb may slowly improve in function, it does not compare with the one from which a clot has been successfully extracted.

When the patient arrives after forty-eight hours, an amputation should not be delayed if there is any chance of saving his life. It takes considerable courage and optimism to urge amputation. The mortality under these conditions is around 50 per cent. I have two patients who have lived over two years after amputation. In each case the leg had to be amputated because of acute arterial occlusion, and the patients bear eloquent testimony as to the value of not giving up the fight too soon. Naturally, moribund patients should not be subjected to any further ordeal.

Mention should be made of multiple peripheral emboli. When they pass from one extremity to another or to the brain, heart, kidney or intestine, the fight has been lost. It must be emphatically stated, however, to physicians who are skeptical of all therapeutic efforts in the treatment of embolism, that the majority of emboli are single for many months, at least, and that patients may lead a useful although physically limited life for many years. Two patients of mine do their own housework, one woman lived for several years and died of multiple sclerosis, one man, who had a cerebral and two peripheral emboli after a myocardial infarct, lives after two years and is capable of moderate activity.

ARTERIAL THROMBOSIS

It has already been mentioned that, although often easily differentiated, thrombosis occasionally is indistinguishable from embolism. Arterial thrombosis may result from mechanical causes, such as pressure from a crutch or a cervical rib, from burns and from frost bites, it may occur during the course of infectious diseases, such as pneumonia, typhoid fever and typhus, and in association with Buerger's disease or arteriosclerosis. With the latter two diseases it may produce the first clinical symptom and appear so suddenly that one is easily led to think of an embolus. Of course all the measures previously outlined for the treatment of acute arterial occlusions, except embolectomy, must be employed. The suture of a vessel which is the site of local thrombosis must invariably lead to renewed thrombus formation. There is, however, another surgical procedure which often improves circulation, that is, excision of the thrombosed vessel. The thrombosed vessel, just like the one which harbors an embolus, maintains a continuous reflectoric vessel spasm, which is responsible for the coldness, numbness, cyanosis and pain of the affected extremity.

While Leriche¹⁶ has advocated excision in the treatment of Buerger's disease and of arteriosclerosis, I feel

that its use is limited to short, well localized segmental clots following trauma or infection. I have recently seen in consultation a young lad who, in falling from a horse on a sharp object, cut his femoral artery, which had to be tied because of massive hemorrhage. Several months later, when admitted to the Research and Educational Hospital, he had a lot of cyanosis and coldness and had lost a few toes. It could easily be demonstrated with the help of sodium nitrite that some of his circulatory impairment was on a vasospastic basis. As the femoral pulse was well palpable in the groin, the arterial segment to be excised was readily demarcated and its removal advised.

Another confusing picture is that of multiple arterial thromboses, which just because of their multiplicity, simulate embolism. It has been suggested that the clotting mechanism is at fault, although the etiology is entirely obscure.¹⁷ Periarteritis nodosa may also give rise to acute arterial occlusion and may easily be due to an allergic manifestation of a chronic vascular infection. A patient with multiple sclerosis had arterial thrombosis in the popliteal fossa which resulted in gangrene and amputation. This is interesting in the light of the recent work of Putnam¹⁸ on the etiology of multiple sclerosis.

VENOUS HEMORRHAGE

Aside from those caused by accidental venous puncture, the majority of venous hemorrhages result from previously existing large varicose veins. Patients with large, thin-walled varicose veins are often afraid of this complication, and yet, although the fact is rather amazing, few of these varices ever produce external hemorrhage. The reason is that usually by the time the skin is thinned out and ready to burst, local phlebitis has formed around the vein, which thickens the wall or may produce thromboses. The varicose vein which is apt to bleed is uninfected and thin walled and shines through the parchment-like skin like a small blue marble. When one recognizes such a vein before or even after it has bled, it is wise to inject it with a mild sclerosing solution, such as a 5 per cent solution of potassium or sodium oleate, and thus prevent hemorrhage.

Loss of blood from a ruptured varix may be considerable, and I have seen a few exsanguinated patients. Usually, well meaning first aid experts put a tourniquet above the bleeding point, which is unnecessary and if not tight enough will only increase venous bleeding. It is enough to elevate the leg high on pillows and apply an even, snug bandage from the toes to above the point of bleeding, in order to control oozing. Secondary infection or ulcer formation rarely follows such an event because the surrounding skin is normal and will readily heal. Some patients with congenital vascular anomalies, such as arteriovenous fistulas or aneurysms, frequently bleed from small, pinpoint primary aneurysms in the skin. For these, roentgen therapy or radium offers a good protection against further hemorrhages.

VENOUS THROMBOSIS

The clotting of blood in the veins is a true vascular accident, as it comes on unexpectedly and with symptoms alarming to the patient. On the upper extremity

venous thromboses are comparatively rare. There are, however, two typical forms of thromboses in the upper extremities, the first is ascending thrombosis of the cephalic or the basilic vein following the introduction of irritating substances, such as hypertonic salt solution, dextrose or dyes, or blood transfusions. The treatment is rest, elevation and hot fomentations. A breaking loose of the thrombus hardly ever occurs.

Another infrequent but characteristic type of thrombosis is that of the axillary or the subclavian vein. This may be of traumatic origin, following pressure on crutches in the armpits, fractures or dislocations of the humerus, or extirpation of axillary lymph nodes requiring extensive dissection around the skin. A typical but rare picture is subclavian thrombosis following prolonged muscular strain during which the vein is compressed between the costocoracoid fascia, the subclavius muscle and the bony chest wall.¹⁹ The diagnosis of such venous obstruction can be made by the history of a sudden strain followed by swelling and cyanosis, the development of collateral veins and sometimes a palpable clot in the axilla or under the pectoral muscle. The stripping or the excision of the thrombosed segment hastens the development of collaterals. In one of my cases, stripping of the axillary vein hastened the disappearance of edema and abolished some vasomotor phenomena, such as flushing and a burning pain brought on by exercise.²⁰

By far the overwhelming majority of venous thromboses occur in the lower extremities. It is convenient to separate them into four groups.

First, the superficial but not varicose vein may be affected. Spontaneous thrombosis of the normal saphenous veins occurs mostly in males. It produces visible and palpable streaks along the inflamed vessel but usually little change in pulse and temperature. The phlebitis may be tubular and ascending or occur in round or oval patches, jumping intact segments of the vein. There is little, if any, swelling of the calf or ankle. The natural course of the disease is slow regression and frequent recurrence. In the majority of cases, typical Buerger's disease later develops, with involvement of the arteries. Other types of segmental phlebitis, which may migrate to the neck, arms or face, include streptococcic, rheumatic and tuberculous forms, but I have seldom seen them.

The second form is thrombosis in varicose veins, which exhibits essentially the same symptoms. There may be, however, much more redness and swelling, and the size of the clots may approach the size of a walnut or even a tangerine. Because of the width of the saphenous vein, massive thrombosis may ascend rapidly from hour to hour toward the groin. In the patchy type of phlebitis, large areas of periphlebitic edema and induration develop, which are painful to the touch, break down easily and form the base of indolent, profusely secreting thrombophlebitic ulcers. Again, the pulse and the temperature may not be affected in spite of the striking inflammatory reaction in and around the vein.

The third form is thrombophlebitis of the deep veins. This presents an entirely different picture. An early sign is a stepladder type of pulse, a rise in temperature is often present but is not characteristic. There may be pain on pressure over the instep or over the calves. The pulses of the foot are diminished as the femoral artery

contracts because of the irritation of its vasoconstrictors. Later the skin of the toes becomes warmer on the affected side²¹ and there is a slight swelling in the groin. All these signs are prodromal, and should the clot remain small or remain localized in the pelvic veins, no further signs develop and the thrombosis is overlooked. Should the clot occupy branches of the hypogastric vein, such as the perivesical, perirectal, perimurine or periprostatic plexuses, edema of the limb will not develop (fig 2). Frequent micturition, mucous diarrhea and slight swelling of the suprapubic region are signs suggestive of pelvic thrombosis. Only when a clot breaks loose suddenly and produces pulmonary embolism or when, months or years later, atypical varicosities develop on the lower extremities, will it become clear that small short clots in the pelvis, not obstructing the external iliac veins, have been overlooked.

When the thrombophlebitis is typical and fully developed, however, after the prodromal signs or often

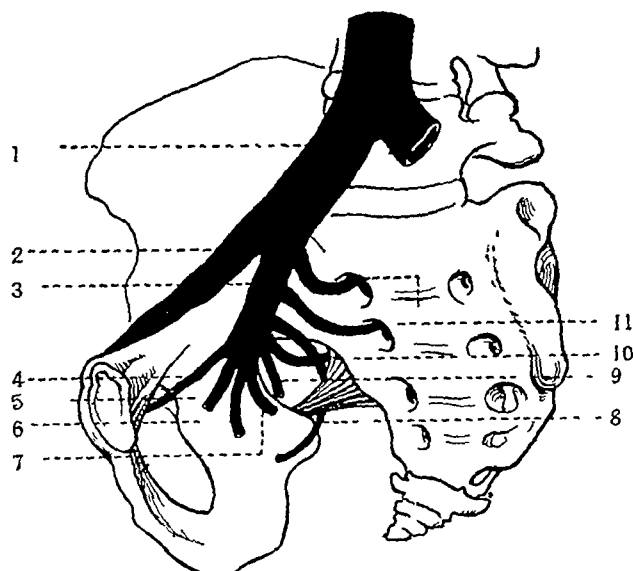

Fig 2—The fanwise distribution of the internal iliac (hypogastric) vein in the pelvis. From Ducuing J. Phlebitis thromboses et embolies postopératoires. Paris: Masson & Cie, 1929, by courtesy of the publishers. The inferior vena cava divides at the upper margin of the sacroiliac articulation. The internal and external iliac veins unite at a sharp angle. Veins: 1 common iliac, 2 external iliac, 3 hypogastric, 4 obturator, 5 middle vesical, 6 uterine, 7 middle hemorrhoidal, 8 internal pudic, 9 sciatic, 10 gluteal, 11 lateral sacral. Phlebitis of these branches may cause peculiar and simultaneous localizations of edema or abscesses in the vulval, gluteal, sciatic or retrosacral regions.

without them a sudden excruciating pain is felt in the groin, followed by a rapidly increasing swelling of the limb, which is first blue and pits easily on pressure but rapidly becomes white and hard, presenting the so-called milk-leg. The accompanying fever and pain and the general toxic state of the patient diminish the milk secretion of lactating mothers to such an extent that both physicians and the lay public used to think that the milk had wandered down into the legs, hence the name. As Homans²² has pointed out, this white hard edema is due at least in part, to blockage of the lymphatics surrounding the large veins and not only to venous edema. The clot becomes palpable along the course of the femoral vein in Scarpa's triangle, it is painful on pressure.

One should add a fourth form of venous thrombosis in the lower extremities, which is fortunately rare but

is very often fatal. This is thrombosis of the perforating veins of the muscles in the calf of the leg, it produces localized swelling of the calf, which is painful on pressure, runs a febrile course and often produces fatal pulmonary embolism.²³ The clots in the veins of the muscles grow by apposition, hang into the swift current of the deep veins and are easily mobilized or broken loose by muscular action. All three patients with this type whom I have seen, two of them physicians, have died of pulmonary embolism.

In most cases thrombosis has an infectious basis, and therefore a search must be made for the sources of infection. Infections in teeth, tonsils, prostate or cervix should be eradicated even if an etiologic connection is uncertain, as they may act as sensitizers. Thus, acute recurrent tonsillitis easily reactivates slumbering phlebitis. The removal of foci is best undertaken during a quiescent, chronic stage, a too early search for foci aggravates a latent infection. I have seen fatal pulmonary embolism follow a tonsillectomy undertaken to calm down slowly receding phlebitis.

The superficial type of thrombophlebitis requires elastic support in the form of bandage, stocking, elastic, adhesive tape or a paste of zinc oxide and glycerin. When the patient is seen in the acute stage, roentgen therapy in small doses (from 95 to 100 roentgens with a heavy filter) is given two or three times at ten day intervals. This produces a remarkable regression of the periphlebitic exudate. Rest in bed, elevation of the affected part, hot wet packs or an electric cradle are necessary for only a few days until the fever and pain disappear. Afterward the patient is not immobilized. Prolonged immobilization of patients with the superficial type of phlebitis is not necessary and may even favor the formation of a clot in the femoral vein. Should the thrombophlebitis be tubular, rapidly ascending and accompanied by fever or chills, ligation of the saphenous vein at the saphenofemoral junction is indicated. This prevents further ascent of the clot and beneficially influences the phlebitis by relieving it from fluctuations of pressure coming from above.

In the treatment of deep thrombophlebitis or phlebitis of the communicating veins, one must try to combat (1) embolism, (2) ascending thrombosis and (3) persistent edema. Once the diagnosis of thrombosis in the deep or perforating veins is made, the patient must be immobilized with the limb slightly elevated under a heat cradle. In most cases, first the temperature and then the pulse will return to normal. It has been my custom to wait ten days after the evening pulse has become normal and then to allow sitting up, slight active exercises and a few steps. Should the pulse rate increase again, further immobilization is necessary. The sedimentation rate, if available, is an excellent guide as to the activity of the clot.

In some cases fever persists for many weeks, the white count remains high and secondary anemia develops. In a physician's daughter I saw the development of mild endocarditis, with the production of a murmur. Other patients will show one or two showers of pulmonary emboli. For such patients especially when they are septic, ligation of the iliac vein above the thrombosis must be seriously considered.²⁴ In weighing the results of such a ligation, it must be remembered that the venous obstruction is already

present and that the additional ligation will not add to the venous embarrassment if important venous collaterals are avoided. When treatment is successful, the temperature promptly drops and the danger of embolism is minimized.

The next consideration is the emergency treatment of pulmonary embolism, which occurs comparatively infrequently in cases of massive thrombophlebitic edema when the condition is recognized and the patient immobilized, but much more often in association with unrecognized pelvic clots or thrombosis in the perforating veins of the calf. Patients die as a result of a massive pulmonary embolism in a few seconds in several hours or in several days. Roughly 50 per cent of all patients die before any medical or nursing help can arrive, but the other half live at least fifteen minutes. In some instances an extraction of the clot has been attempted, and of over 100 such attempts, nine were successful.²⁵ The three great handicaps in the performance of successful operations are (1) the confusion of pulmonary embolism with coronary thrombosis, (2) the absence of a properly trained and equipped surgical team in most communities and (3) the recurrence of pulmonary embolism after a successful embolectomy. The operation at present is to be regarded as an interesting, desperate effort or a stunt, and its wide adoption is not to be expected. More important are some simple measures, which can be used even in the home. If the patient is cyanotic, oxygen should be administered by mask or, better, by an intranasal catheter. One-half grain (0.03 Gm.) of papaverine, as in the treatment of embolism of the peripheral arteries, overcomes the accompanying vessel spasm. If the blood pressure has fallen to 90 mm. of mercury or below, its cautious elevation with ephedrine or neosynephrine may be tried. Too sudden elevation may press more clots through from the right side of the heart, although this is a theoretical consideration.

Should the embolus be small and the patient recover from the immediate danger, bloody sputum, a pleural friction rub and a roentgenogram of the chest will indicate the size and location of the infarct. The best treatment is prevention of further emboli. This is the time, if the location of the original thrombus is recognized, for a prophylactic ligation proximal to the clot.

The last but practically very important consideration is the prevention of future persistent edema of the leg afflicted by deep venous thrombosis. The treatment must really begin on the day of the formation of the clot. Every effort must be made to rid the limb of the swelling, as persistent edema, rich in protein, will produce permanent fibrosis of the subcutaneous tissue.²⁶ To this end, fluids are restricted to 1,000 cc. a day, salt is restricted and ammonium chloride or nitrate is given in 15 grain (1 Gm.) doses four times a day. The limb is maximally elevated and a heat cradle is applied. Two or three days later a mercury diuretic such as salyrgan is given intravenously, not more than 0.5 cc. at first and 1 cc. two days later. The intravenous administration of calcium gluconate has also proved helpful.²⁷ All these drugs tend to mobilize fluid from the edematous limb, and if the edema subsides it is much easier to prevent further swelling by elastic support than if the patient is allowed to get up with a

swollen limb. After the patient gets out of bed, elastic support must be maintained for a year or longer. Even so, a lasting reduction of the swelling cannot be predicted or promised, as it will depend on the length of the clot and on the extent to which the tributary veins are plugged.

This emergency treatment of deep venous obstruction is again in the hands of the general practitioner. When the patient is seen years after onset, the fluid has become fixed, the lymphatics are destroyed and the tissue is fibrous. At that stage only extensive excision of the diseased tissue can help, but this is to be undertaken only in cases of extreme involvement, in which stasis of lymph predominates.

SUMMARY

The first aid given for vascular accidents of the extremities, such as arterial hemorrhage, embolism and thrombosis and venous hemorrhage and thrombosis will often determine the future course and the recovery or disability of the affected limb. With simple measures available to every physician, the majority of accidents can be adequately handled. In larger communities, the younger surgeons can prepare themselves for the surgical treatment of these emergencies, which often consists of limb-saving or life-saving measures.

THE EFFECT OF VITAMIN B₁ ON THE PERIPHERAL NEURITIS OF PELLAGRA

TOM D SPIES, M.D.

AND

CHARLES D ARING, M.D.

CINCINNATI

Pellagra has come to be accepted as a clinical syndrome characterized by symptoms referable to the alimentary tract and the dermal and neural systems. The literature on the mental changes in pellagra is extensive, but relatively few observations have been reported on the involvement of the peripheral nerves. While studying so-called alcoholic pellagra a number of years ago, Spies and DeWolf¹ were forced to the conclusion that alcohol is not the sole cause of the neuritis accompanying this disease. The correctness of this point of view has been established by Strauss,² Jolliffe, Colbert and Joffe,³ Spies and Blankenhorn,⁴ Romano⁵ and Goodhart and Jolliffe.⁶

During our studies on the peripheral neuritis associated with pellagra we noted that we could not distinguish it from the peripheral neuritis of beriberi. This observation led us to administer large amounts of yeast, wheat germ and liver extract to patients with

deficiency diseases and accompanying neuritis. Having obtained successful results with this method of therapy, we undertook controlled studies, using crystalline vitamin B₁. These studies form the basis of the present report.

MATERIAL AND METHODS

Six cases of classic pellagra were selected for the study of peripheral neuritis. In four, pellagra had developed after the substitution of the calories of alcohol for the calories ordinarily obtained from food. In the remaining two cases the pellagra was unassociated with chronic alcoholic addiction (the so-called endemic type of pellagra). It has been pointed out previously⁴ that the severe peripheral neuritis associated with pellagra usually progresses when the patient is restricted to a pellagra-producing diet. The vitamin B₁ crystals (aneurin, torulin, thiamin) given as supplements to the pellagra-producing diet used in this study were supplied through Dr. Hans Molitor of Merck & Co. Histories of two representative cases of pellagra with involvement of the nerves follow.

CASE 1—History.—G. S., a Negro woman, aged 34, was admitted to the medical service of the Cincinnati General Hospital on Dec. 7, 1937. About ten months previously her husband had gone "on relief," which made it necessary for five adults, including the patient, to subsist on \$6 a week. Three months before the patient's admission to the hospital her appetite became very poor, and a month later she began to note numbness, pain and tingling in the feet and legs. Her tongue became sore at about this time. One month before her admission a scaly, dry and symmetrical eruption appeared over the dorsa of both hands. One week later the same type of dermal lesion developed beneath the breasts and about the vagina, and the lesions on the hands spread to involve the flexor and radial surfaces of the forearms up to the elbows.

At about this time the patient's physician prescribed a diet consisting of milk, greens and an occasional egg and told her to eat no meat. She lost weight rapidly on this regimen. Shortly thereafter numbness was observed in the upper extremities and the trunk. December 3 she lost consciousness for about two hours. On regaining consciousness, she was delirious, salivated profusely and apparently could not move her lower extremities. Thereafter she continued to salivate profusely, was apprehensive and weak and complained of soreness of the mouth.

The past history contained nothing related to her condition at the time of admission to the hospital, with the single exception that she had partaken moderately of alcoholic beverages and had occasionally overindulged. However, she had not done so within three or four years prior to admission.

Examination.—There were dark, dry, scaly lesions, symmetrical and well demarcated, on the dorsa of both hands, along the flexor and radial surfaces of the forearms and over the elbows. The same type of lesion was present beneath the breasts, in the skin of the perineum, in the sacral region, over the dorsa of the feet and about the ankles. The lesions beneath the breasts were macerated and reddened and exuded serum. The tongue was smooth and scarlet, and the entire buccal membrane was very red as were the margins of the gums. The gums were partially covered by a thick Vincent's membrane. The openings of Stensen's ducts were enlarged and reddened. The lips were swollen and cracked. The patient was salivating profusely. The blood pressure was 98 systolic, 60 diastolic.

Neurologically she presented several abnormalities. She was dull and could not concentrate or cooperate for any length of time. Her responses were unreliable and she was very apprehensive and occasionally became excited. There were mild wasting of the muscles in the gastrocnemius group in the legs, tenderness in the muscles of the lower extremities and diminution in the perception of touch, pain and temperature below the knees. All of the tendon reflexes were very active with the exception of the ankle jerks, which could not be elicited. Left patellar clonus was present.

The blood count showed 3,500,000 red cells, which were normal in size and color. The hemoglobin content was 11 Gm per hundred cubic centimeters. The white cells ranged between 4,200 and 8,200, with a normal differential count. Examinations of the urine and the stools gave normal results, except that large quantities of coproporphyrin were excreted in the urine. The excretion returned to normal after the administration of nicotinic acid. The carbon dioxide combining power was 43 volumes per cent. The blood urea nitrogen content was 9 mg and the serum protein content 5.9 Gm per hundred cubic centimeters. The Wassermann reaction of the blood was positive on one occasion and negative on two others. The Kahn reaction of the blood was positive, with sensitized antigen, on three occasions. Myriads of Vincent's organisms were demonstrated in smears from the gums, the vagina and beneath the breasts.

Progress.—On admission (Dec. 7, 1937), the patient was placed on a pellagra-producing diet. This diet included corn meal, hominy, white flour, sugar, pork fat, sweet potatoes and small amounts of cabbage and collards. It resembles Goldberger's and Wheeler's diets more than any of the other deficient diets; the total calories are adequate, the protein is low and the minerals (calcium, phosphorus and iron) are low. It is adequate in its vitamin A and C content but low in vitamins B, D and G.

On December 7, 500 mg of nicotinic acid was given orally in doses of 100 mg every half hour. Transitory itching of the dorsa of the hands and wrists followed. Thereafter 1 Gm of nicotinic acid in a 1 to 1,000 solution was administered daily until the patient's discharge from the hospital (200 cc of the solution orally five times a day). On December 8 the buccal mucous membranes were less red. Stensen's ducts were not as prominent as they had been at the time of admission, and the salivary secretion, of which the patient expectorated 2,000 cc during the first twenty-four hours in the hospital, dropped to 50 cc of expectoration within forty-eight hours. The mucous membranes of the oral cavity and the vagina healed within twenty-four hours after the nicotinic acid therapy was begun, but the dermal lesions healed slowly and the peripheral neuritis became worse, in that the spontaneous pain, the numbness and the pain caused by handling the feet were much more severe. The intravenous injection of 10 cc of sterile saline solution for three days, beginning December 14, did not have any therapeutic effect (suggestion). By this time Vincent's organisms had disappeared from the mouth, vagina and lesions of the skin.

On December 17 and daily thereafter 50 mg of crystalline vitamin B₁ in sterile physiologic solution of sodium chloride was injected intravenously. The diet was not altered. On December 19 the patient volunteered that the pain and numbness in the legs had disappeared, and her appetite became voracious. She complained of having too little to eat, though she was given the basic diet. She became cheerful and lost apprehension, she was alert and her responses to sensory tests were accurate for the first time. There was no change in the other results of neurologic examination except that muscular tenderness in the lower extremities was obviously diminished. Her weight, which was 123 pounds (56 Kg) on December 12, had increased to 131½ pounds (59.6 Kg) by December 18. On December 22 she was able to get out of bed for the first time since admission and she walked without difficulty. On December 26 her weight was 141½ pounds (64.2 Kg). She was given a well balanced diet for a few days prior to discharge. She was discharged from the hospital much improved on December 29. The dermal lesions of the hands and forearms had disappeared, and those beneath the breasts and about the perineum had healed, leaving only residual pigmentation.

CASE 2—History.—C. S., a white man aged 52 was admitted to the medical service of the Cincinnati General Hospital on Oct. 27, 1937. Since April 1937 his regular diet had been gradually replaced by whisky, so that by May 1937 he was consuming from 1 to 2 pints daily. In mid June dermatitis appeared on the dorsa of the hands and on the elbows. Two weeks later these areas were reddened, tough and blistered. At this time the patient's tongue became sore and very red and shortly thereafter pains in the legs which radiated down to the toes, developed.

On July 13 he entered the St Elizabeth Hospital, Covington, Ky, where a diagnosis of pellagra and polyneuritis was made. We saw him there Six ounces (180 cc) of dry powdered brewers' yeast was administered each day, and at the end of two weeks his dermal lesions began to recede, but severe diarrhea (fifteen stools daily) developed, which lasted for two weeks. The diarrhea, dermatitis and glossitis were finally relieved by the therapy, and he was discharged on August 24. However, the radiating pains in the legs and feet steadily became worse, and by mid-August he could not bear the weight of bedclothes on his lower extremities. In early September the pain no longer radiated, it became constant and was confined to the knees, legs and feet. There was an intense burning sensation on the soles of the feet.

Examination—The examination performed when the patient was admitted to the Cincinnati General Hospital, on October 27, showed that he was poorly nourished, the tongue was coated and the skin on the dorsa of the hands and elbows presented residual changes of pellagrous dermatitis. The blood pressure was 118 systolic, 80 diastolic.

Neurologic examination revealed that there were six or seven nystagmotic jerks when the patient fixed his eyes to the right or left, the tongue was tremulous and there was some muscular atrophy in the interosseous and the lumbrical muscles, in the thenar and the hypothenar eminences of both hands and in the thigh muscles. The hand grasps were moderately weak, but no other loss of motor power was demonstrable. There was marked tenderness to deep pressure in the muscles of the feet, legs, forearms and arms. The recognition of pain, temperature and touch stimuli was diminished in the lower extremities up to a point about 3 inches above the knees and in the upper extremities up to the insertion of the deltoid muscle. This border was not a sharp one. The appreciation of vibration was diminished about one half in the extremities and even more so in the lower extremities. Fine passive changes in the position of the toes were not appreciated by the patient, however, he named large displacements properly. He was extremely sensitive to stroking of the soles of the feet. The tendon reflexes were normal with the exception of the ankle jerks, which were not obtained. The plantar responses were normal in the right foot, there was no response to plantar stimulation in the left foot.

The blood count showed 5,000,000 red blood cells, which were normal in size and shape. The hemoglobin content varied from 13.8 to 15.6 Gm per hundred cubic centimeters. The white cells ranged from 6,400 to 9,600, with normal differential counts. The sedimentation rate was 16 mm an hour (corrected rate). The Wassermann and the Kahn reaction of the blood were positive. Gastric analysis showed no free hydrochloric acid before or sixty minutes after the injection of $\frac{1}{2}$ grain (0.003 Gm) of histamine. The pressure of the cerebrospinal fluid was normal, there were 2 lymphocytes in a blood tinged (trauma) fluid. The total protein content was 72 mg per hundred cubic centimeters and the chlorides 701 mg. The Wassermann reaction of the cerebrospinal fluid was negative.

Progress—On October 30 the patient was placed on a basic diet low in vitamin B and on November 3 on the basic diet used in case 1. From November 3 through November 8 he was given small amounts of physiologic solution of sodium chloride intravenously (for its suggestive effect), but he noted that this medicine was "not so good," as he had constant pain and burning sensations in his legs. By November 9 weakness had progressed to such an extent that movements about both ankles were very weak, the left ankle being worse than the right. Flexion and extension of the forearms were definitely weak. From November 9 through December 3 he was given a daily intravenous injection of 50 mg of crystalline vitamin B₁, receiving twenty-five injections in all. On December 10 he ceased complaining of pain, and by the eleventh he volunteered that there was complete remission of spontaneous pain. On December 14 he walked with ease and without pain for the first time since admission. Whereas salicylates, aminopyrine, barbitol and 2½ grains (0.02 Gm) of codeine daily had been necessary to control the pain before the use of crystalline vitamin B₁, no analgesic was required as long as administration of the vitamin was continued.

The neurologic status was checked daily, and on December 13 the significant observation was diminution of motor power in all the muscle groups of the extremities, more obvious in the distal structures and greater in the lower left extremity than in the right. Only the slightest movement was possible in the left toes and the left ankle. There was diminution of all types of sensation in the distal portions of the extremities, and sensation gradually (no sharp border) approached normal just above the patella and the elbow. Touch was not appreciated in the lower third of the left leg or in the left foot, and the patient was unable to identify pin prick in the left leg until the upper border of the patella had been reached, although he realized that there was "something dull" in the leg when it was stimulated below that level. The same phenomenon was present in the right leg, where the level of identification of pin prick was at the junction of the upper third with the lower two thirds of the leg. The appreciation of vibration was diminished about one half over the malleoli. Position sense was poor in the left toes but good in the right. There was tenderness to pressure in the muscles of the feet, legs and arms, especially over the nerve trunks. There was no complaint of spontaneous pain. The only abnormal tendon reflexes were hypo-active knee jerks, and the ankle jerks were not elicited. It was noted from the neurologic examinations that there was no improvement, with the single exception of the remission of spontaneous pain.

The patient continued to improve, even though the injection of vitamin B₁ was discontinued on December 3. His weight increased and his motor power slowly improved. However, on December 24 he complained of some pain in the axillae, and examination of these regions revealed tenderness about the brachial plexus. In late December and early January spontaneous pain increased and was worse in the upper than in the lower extremities. Sharp radiating pain traveled from the axillae down the arms and into the forearms, and down the posterior surface of the thighs and legs to the feet. By January 3 the motor status had regressed to that noted on December 13, and the patient was extremely tender along the course of the nerves in the axillae, arms and forearms. His weight had improved from 107½ pounds (48.8 Kg) on November 7 to 116 pounds (52.6 Kg) on January 1.

COMMENT

The experience detailed in these two cases was similar to that in the remaining four. Irrespective of whether the pellagra followed long-standing ingestion of alcohol, the prompt relief of the spontaneous pain of neuritis by the intravenous injection of crystalline vitamin B₁ was striking in all cases. Nicotinic acid by mouth was used in three cases and completely relieved the severe stomatitis and glossitis and promptly produced healing of all the lesions of the mucous membranes. The observations suggest that the painful peripheral neuritis in these particular cases was caused, at least in part, by a lack of vitamin B₁. The response following the injection of this substance was prompt and dramatic. These studies complement the suggestion offered a number of years ago that the clinical manifestations of the pellagra syndrome are perhaps caused by a lack of more than one essential substance. Not all persons with pellagra, however, have peripheral neuritis.

While these pellagras responded to a basic diet plus supplements of nicotinic acid and thiamin (vitamin B₁), it is not recommended that such a diet be used in the treatment of pellagra.

SUMMARY AND CONCLUSIONS

1 Our observations suggest that vitamin B₁ deficiency had a role in the development of the clinical manifestations of peripheral neuritis associated with the pellagra in these cases.

2 Certain patients fail to absorb vitamin B₁ effectively by mouth, and it is imperative that they be

given parenteral injections. Parenteral injections shorten convalescence and are desirable from the standpoint of prompt relief of pain.

3 Vitamin B₁ does not cure the glossitis and the stomatitis of pellagra,⁷ but the observations in case 1 and in other cases suggest that nicotinic acid, which does cure these symptoms,⁸ will not cure the peripheral neuritis.

THE TREATMENT OF METASTATIC CARCINOMA OF THE NECK

SECONDARY TO CARCINOMA OF THE LIP

R. B. MORELAND, M.D.

HINES, ILL.

My purpose in this paper is to present rather briefly what appears to be the best treatment for metastases to the neck from carcinoma of the lip.

Results obtained by the irradiation of cervical metastases have been reported by Schreiner and Mattick,¹ Schreiner and Simpson,² Dund and Holton³ and others. The diagnosis of cervical metastases in these cases was made clinically. The question always arises in one's mind as to how many of these patients would have had microscopically negative glands. This number would probably vary widely in different series. Bloodgood⁴ has stated that he found the clinical diagnosis of metastasis proved wrong much more frequently than the reverse.

Results obtained by surgical intervention have been reported by Fischel,⁵ Wangenstein and Randall,⁶ Eggers⁷ and Kennedy.⁸ Glands removed were examined microscopically. It is difficult, however, to classify and compare cases clinically. Different conceptions are had concerning what constitutes a neck clinically negative for metastases, what patients have glands which clinically show only inflammatory hyperplasia, what patients have glands which clinically show metastases, and lastly what constitutes the limit of operability.

Results from the combined irradiation and surgical treatment have been reported by Quick,⁹ Martin,¹⁰

Hyndman¹¹ and Scott.¹² Results are the best, I believe, from this type of treatment. This is the type of treatment advocated in this paper. It has been my observation that one is less biased in one's selection of the method of treatment to be followed in a particular case when all methods are equally available and that better judgment can usually be exercised by one familiar with the various methods of treatment.

Broders¹³ has shown a definite relationship between the histology of the lesion and the results obtained by treatment.

An interesting study has been made by Pflueger,¹⁴ reporting the type of treatment given by thirty prominent radiologists, dermatologists and surgeons. Because of the difficulties mentioned, it is difficult to compare the results obtained by these various men and their methods of treatment.

In my opinion the neck should not ordinarily be treated until the primary lesion has been treated and controlled. The primary lesion may be successfully treated, in a very high percentage of cases, by surgery, radium or x-rays. Good surgery is better than poor irradiation, and vice versa. Some lesions, however, are better treated by irradiation, others by surgery. Very briefly, anaplastic tumors of grade 3 or 4 malignancy are more suitable for irradiation. The agent employed is less important in more differentiated tumors of low grade malignancy. As in the treatment of all other tumors, there is a necessity for familiarity with exactly what can be accomplished by both surgery and irradiation. It has become my custom, in order to avoid delay in treating the neck, when operable metastatic glands are present, to excise the lesion of the lip and about two weeks later do a dissection of the neck.

It is generally agreed that cancer metastasis is an embolic phenomenon and that carcinoma cells cannot be demonstrated in the lymphatics or other tissues between the primary lesion and the metastases.

Numerous reports have shown that in carcinoma of the lip remote metastases occur in less than 1 per cent of the cases, and metastasis to the regional lymphatics in from 20 to 25 per cent of the cases.

Lesions most apt to metastasize are (1) those of high grade malignancy, especially grades 3 and 4, (2) infiltrating tumors (papillary lesions are less likely to metastasize), (3) rapidly growing lesions, and (4) previously treated lesions, especially those improperly and inadequately treated. It has been observed that the incidence of cervical metastasis is higher in lesions previously treated with paste or other types of escharotics.

Prophylactic irradiation is not given to the neck.

Nodes that are thought to be inflammatory are watched. If there is much doubt or if the nodes are thought to be metastatic, dissection of the neck is done. Preoperative irradiation is not given. Postoperative irradiation (from 3000 to 4,000 roentgens through two portals) is given in all cases in which the glands removed show carcinoma microscopically. The reason for giving postoperative irradiation is that it is believed, although it has not been proved, that any persistent cells are more sensitive for a short time following surgery. This opinion was recently expressed

by Sir Lenthal Cheatele¹⁵ of London, England, in discussing carcinoma of the breast Dr Cheatele also recommends washing out the wound at the completion of the operation with 1 500 solution of mercury bichloride, as he believes that this is likely to destroy any loose tumor cells

I find no definite proof of the value of irradiation when given prophylactically to the neck or when given when the nodes are palpably enlarged If the nodes disappear, there is no microscopic evidence that the

and the carefulness of his examination It is better to err by removing some nonmalignant glands than to defer surgical operation for observation of the patient, especially if the patient cannot be watched closely

There are many types of so-called neck dissections Some men mean merely removal of the gland involved, others, block removal of all lymphatics, from the clavicle to the base of the skull, including the sternomastoid muscle, internal jugular vein and other of the soft tissue structures on one or both sides, some

TABLE 1—Ten Cases of Carcinoma (Squamous Cell Keratinizing) of the Lip No Evidence Clinically of Metastases in the Neck

| Case No | Date | Name | Primary Lesion | Pre operative Irradiation | Type of Operation | Glands Microscopically | Post operative Irradiation | Result |
|---------|---------|-------|------------------------|---------------------------|--|------------------------|----------------------------|-------------------|
| 1 | 7/24/34 | R K | Advanced grade 2 | Yes | Bilateral suprahyoid | Negative | Yes | Well October 1937 |
| 2 | 1/23/35 | W H | Left lip 2 by 3 cm | Yes | Bilateral suprahyoid | Negative | No | Well October 1937 |
| 3 | 2/14/35 | D H | Right, 2 cm | Yes | Bilateral suprahyoid | Negative | No | Well October 1937 |
| 4 | 2/15/35 | R G | 1.5 cm grade 2 | No | Right submaxillary node excised | Negative | No | Well October 1937 |
| 5 | 3/23/35 | W R B | 2 by 3 cm | No | Bilateral suprahyoid | Negative | No | Well October 1937 |
| 6 | 4/ 7/35 | E A L | 2 cm right | No | Bilateral suprahyoid | Negative | No | Well October 1937 |
| 7 | 4/ 9/35 | T J M | 1 cm left | No | Bilateral suprahyoid | Negative | No | Well October 1937 |
| 8 | 4/20/35 | B S | 2 cm grade 3 | No | Bilateral suprahyoid | Negative | No | Well October 1937 |
| 9 | 5/ 8/35 | E E D | 1 cm left superficial | No | Bilateral suprahyoid | Negative | No | Well October 1937 |
| 10 | 5/15/35 | F B | Papillary 1 cm grade 2 | No | Bilateral suprahyoid and left upper cervical | Negative | No | Well October 1937 |

In these ten cases in which the neck was clinically negative for metastases the glands were microscopically negative in all ten cases It is believed that operation was unnecessary in these cases All the patients are living and well

TABLE 2—Fifteen Cases of Carcinoma (Squamous Cell, Keratinizing) of the Lip Clinical Evidence of Early Operable Metastases in the Neck

| Case No | Date | Name | Primary Lesion | Neck | Type of Operation | Glands Microscopically | Post operative Irradiation | Result |
|---------|----------|-------|--|--------------------------------------|---------------------------------|---|----------------------------|--------------------|
| 1 | 11/24/34 | M S | Treated for 10 yrs | Hard right submaxillary | Bilateral suprahyoid | Positive | Yes | Well October 1937 |
| 2 | 1/29/35 | L A | Recurrent | Hard right submaxillary | Right submaxillary node excised | Negative | No | Well December 1936 |
| 3 | 2/13/35 | G L F | Right 2 cm grade 2 | Firm right submaxillary | Bilateral suprahyoid | Negative | No | Well October 1937 |
| 4 | 3/ 8/35 | F B | 3 cm 3 yrs midline, grade 3 | Hard submental and left submaxillary | Bilateral suprahyoid | Positive bilateral | Yes | Well October 1937 |
| 5 | 4/26/35 | P R | 1 cm right 2 yrs grade 2 3 | Hard right submaxillary | Bilateral suprahyoid | Positive right | Yes | Well January 1936 |
| 6 | 11/22/35 | C H | 1.5 cm right grade 2 3 | Hard right submaxillary | Bilateral suprahyoid | Positive right | Yes | Well October 1937 |
| 7 | 6/ 1/36 | D C | 1 cm right recurrent grade 1 2 | Submental small firm | Bilateral suprahyoid | Negative | No | Well October 1937 |
| 8 | 7/ 3/36 | W B | Right side grade 2 | Right submaxillary rather soft | Right submaxillary node excised | Negative frozen section positive fixed prep | Yes | Well October 1937 |
| 9 | 7/26/36 | W B | Entire lip 7 cm grade 2 3 | Right submaxillary hard, 1.5 cm | Bilateral suprahyoid | Positive | Yes | Well October 1937 |
| 10 | 10/ 1/36 | E L | Entire lip | Hard submental 2 cm left | Left suprahyoid | Positive | Yes | Well October 1937 |
| 11 | 10/13/36 | W B | Midline lip | Hard submental, 1 cm left | Submental dissection | Negative | No | Well October 1937 |
| 12 | 2/ 3/37 | J P | Previous treatment caustics and radium midline ulcer 1 cm erythema | Submaxillary bilateral 2 cm hard | Bilateral upper neck (2 stages) | Positive bilateral | Yes | Well October 1937 |
| 13 | 4/ 7/37 | G W S | Left 1.5 cm indurated ulcerated | Submaxillary bilateral 2 cm hard | Bilateral upper neck (2 stages) | Positive bilateral | Yes | Well October 1937 |
| 14 | 7/14/37 | R D B | Midline 1 cm indurated not ulcerated treated March 1937 | Submaxillary 2 cm right hard | Right suprahyoid | Positive | Yes | Well October 1937 |
| 15 | 8/ 6/37 | G A P | 12 mm midline ulcerated treated June 1936 | Submental hard 3 cm | Bilateral suprahyoid (1 stage) | Positive | Yes | Well October 1937 |

In these fifteen cases in which there were early operable glands clinically the glands were microscopically positive in eleven cases negative in four cases All the patients are living and well It is believed that operation was justified and indicated in these cases

nodes were metastatic It has been my observation that true cervical metastasis, microscopically proved, developing from differentiated carcinoma of the lip is seldom, if ever, cured by external irradiation, either radium or x-rays, and only rarely by a combination of external and interstitial irradiation

Far advanced, inoperable cases are suitably treated by external irradiation first, and then interstitial irradiation, usually by means of gold implants of radon

It is not always possible to differentiate, clinically, between hyperplastic inflammatory glands and metastatic glands It is believed however, that the number of errors decreases with the experience of the examiner

do a complete neck dissection on one side and a partial or upper neck dissection on the other side

It seems to be the consensus of the best opinion that in carcinoma of the lip, with operable metastasis in the submaxillary or submental nodes, suprahyoid dissection is sufficient Hyndman¹¹ believes that dissection should always be bilateral, because of the frequency, in his opinion of crossed metastasis Quick¹⁶ states that removal of the submental, submaxillary and upper deep cervical glands, on the involved side, gives as good results as the more radical operations It has been my custom to follow the latter procedure except

¹⁵ Cheatele Sir Lenthal Carcinoma of the Breast presented at Michael Reese Post Graduate Tumor Clinic Chicago in September 1936

¹⁶ Quick Douglas Radium in Treatment of Metastatic Epidermoid Carcinoma of Cervical Lymph Nodes Am J Roentgenol 33 677 681 (May) 1935

when the lip lesion is located near the midline or when the lesion is very large or of a highly malignant character. Then, a bilateral suprahyoid and upper deep cervical dissection is carried out. Quick¹⁰ also states that "it is our belief that as satisfactory and successful an operation could be done after a node became palpable as before." This also is my opinion. When metastases occur in the deep cervical glands, a complete neck dissection on the affected side is recommended, saving the internal jugular vein and sternomastoid muscle, unless infiltrated by the growth. An

tually the upper deep cervical lymphatics for inspection and palpation before definitely deciding on the limits of the operation.

Since the Tumor Service was organized at the Edward Hines Jr. Hospital in 1931, there have been 525 cases of true carcinoma of the lower lip treated (1931-1936) in addition to ninety keratoses or other precancerous lesions, or a total of 615 cases. In approximately 22 per cent of the cases of carcinoma of the lip cervical metastases were present or developed later. Many of these cases had been neglected and

TABLE 3—Six Cases of Carcinoma (Squamous Cell, Keratinizing) of the Lip. Clinically the Glands Were Advanced, of Borderline Operability

| Case No. | Date | Name | Primary Lesion | Neck | Type of Operation | Glands Microscopically | Post operative Irradiation | Result |
|----------|----------|-------|--|--|--|------------------------|----------------------------|---|
| 1 | 1/21/35 | F. P. | Advanced—grade 2-3 | Right submaxillary hard, 5 cm, 4 mo. fixed | Right suprahyoid | Positive | Yes | Well October 1937 |
| 2 | 4/20/35 | D. L. | Entire lip 1 yr grade 2-3 | Left submaxillary, hard, ulcerated, fixed | Left suprahyoid and seeds | Positive | Yes | Well October 1937 |
| 3 | 12/20/35 | F. R. | Scar only | Right submaxillary hard fixed cm | Right suprahyoid and seeds | Positive | Yes | Probable recurrence in February 1937, not heard from since |
| 4 | 3/13/36 | W. G. | Treated elsewhere | Right submaxillary hard, fixed 4 cm | Right suprahyoid and seeds | Positive | Refused further treatment | metastasis left submaxillary in June 1936, had surgery and irradiation elsewhere, died April 1937 |
| 5 | 8/28/36 | J. P. | Left 2 cm grade 2 | Left submaxillary, hard 3 cm, partly fixed | Left suprahyoid | Positive | Yes | Well October 1937 |
| 6 | 5/20/37 | F. B. | Indurated scar midline result of paste treatment | Fixed, hard right submaxillary 7 cm, partly fixed, hard left submaxillary, 6 cm, posterior cervical bilateral 1.2 cm (several) posterior irradiation (elsewhere) probably inoperable | Complete bilateral dissection (2 stages) | Positive bilateral | Yes | Recurrence October 1937 |

In these six cases in which there were advanced cervical glands of borderline operability, the glands were microscopically positive in all six cases. Three patients are living and well. One has recurrent carcinoma in the neck, one probably had recurrent carcinoma in neck when last heard from in February 1937, and one died of recurrent carcinoma in the neck. The sixth patient who now has recurrence, had been considered inoperable and a terminal case by a private radiologist and had been given irradiation to the neck. A cure was hardly expected by radical surgery but it was hoped at least to prolong his life.

Unilateral dissection of the upper part of the neck was done in five of these cases because of the patients' general poor condition. The opposite side of the neck was observed. Further treatment was not required in four of these six cases. In many cases of this type it is probably justified and indicated, to do a dissection of the upper part of the neck on the opposite side two or three weeks after the first operation.

TABLE 4—Two Cases of Carcinoma (Squamous Cell, Keratinizing, of the Lip). Clinically Operable Glands, Treated by Simple Node Excision and Implantation of Radon Seeds

| Case No. | Date | Name | Primary Lesion | Neck | Pre operative Irradiation | Type of Operation | Glands Microscopically | Post operative Irradiation | Result |
|----------|----------|-------|--------------------------------|--|---------------------------|---|------------------------|----------------------------|--------------------------------------|
| 1 | 6/29/34 | W. C. | 5.5 cm 14 mos grade 2-3 | Multiple hard glands 1.2 cm | Yes | Enlarged nodes excised and seeds | Positive | No | Died of metastatic carcinoma 9/20/35 |
| 2 | 11/22/34 | P. D. | 2 cm treated 6 mos by caustics | Submental firm 1 cm right submaxillary firm 1 cm | Yes | Enlarged nodes excised and seeds (12/28/34) recurrent nodes excised and seeds (2/19/35) | Positive | No | Died of metastatic carcinoma 12/6/35 |

In these two cases in which there were clinically operable glands, the glands were microscopically positive. External irradiation was given, followed by excision of enlarged nodes and implantation of radon seeds. Both patients are dead of cervical metastases. This treatment is now not recommended for operable cervical metastases.

upper neck dissection may, or may not, be done on the opposite side. Bilateral complete neck dissection is seldom indicated.

As a general principle it is believed that dissection should include not only the anatomic triangle involved but also the two triangles bordering it, that is, the one on each side. For example, for metastasis in the right submaxillary triangle, dissection should include also the submental triangle and the upper deep cervical triangle, anterior and posterior on the right, down to the omohyoid muscle. If metastases are present in the right upper deep cervical triangle, the dissection should include at least the right submaxillary triangle and the entire deep cervical chain, anterior and posterior, including the supraclavicular space. For metastasis in the submental triangle, dissection should include the submental and both submaxillary triangles. It is also frequently advisable, as in this case, to expose par-

were advanced at the time of admission. Many had been previously and improperly treated. It is apparent that this incidence of metastasis is much higher than that when early and adequate treatment is given.

The accompanying tables show the results in the last thirty-three consecutive cases in which dissections of the neck were done during the past three years. All cases had a biopsy diagnosis, but all were not graded microscopically. It has been found difficult to grade some lesions accurately.

Cervical nerve block combined with local infiltration was the anesthesia used in most of the cases. In some, rectal ether supplemented with intratracheal anesthesia was employed. This also is very satisfactory. Avertin with amylene hydrate was abandoned after some untoward reaction in a few cases. There was no operative mortality in this series.

CONCLUSIONS

1 The results in thirty-one cases treated in the manner advocated are very gratifying. Twenty-eight of these patients are free from disease from a few months to more than three years.

2 Dissection of the neck is advocated when the primary lip lesion has been controlled and when there are enlarged cervical glands thought clinically to be metastatic.

3 Preoperative irradiation is not given. Postoperative irradiation, from 3,000 to 4,000 roentgens, is given in all cases in which the glands are microscopically positive for carcinoma.

4 Observation is advocated when enlarged cervical glands are thought to be inflammatory. Improving the condition of the mouth is all that is necessary in most of these cases.

5 When the cervical glands are not enlarged, neither irradiation nor neck dissection is advocated.

6 Neck dissection can be done as successfully after the glands are enlarged as before, provided operation is not deferred until the glands are large, fixed, ulcerated and inoperable.

7 Combined external and interstitial irradiation is employed in far advanced, palliative cases.

8 Probably no other tumor condition is treated in more ways, or regarding which opinion is more divided and treatment less standardized, than in metastatic carcinoma of the neck.

PULMONARY COMPLICATIONS

FOLLOWING 1,333 ADMINISTRATIONS OF CYCLOPROPANE

G. EDGAR BURFORD, M.D.

Director of Anesthesia, St. Luke's Hospital

NEW YORK

During the past five years a new anesthetic gas, cyclopropane, has been gradually introduced into medicine. Its anesthetic properties were discovered in 1929,¹ and its true value has since been established step by step by active cooperation among anesthetists and surgeons,² physicians³ and physiologists and pharmacologists,⁴ particularly those at the University of Wisconsin.

The method of introduction, although the gas is revolutionary in its field, has been a model of cautious statement, completely lacking in the publicity and exploitation that has accompanied lesser events.

The new and unique value of cyclopropane lies in the high oxygen content with which it can be used. For instance, two patients at St. Luke's Hospital were anesthetized directly from an oxygen tent, were returned to the tent after operation and recovered.

Other features of this anesthetic, such as ease and pleasantness of induction,⁵ greater relaxation than that produced by other gaseous anesthetics, quick elimina-

tion⁶ and applicability for special surgical procedures, particularly thoracic operations,⁷ have been stressed in numerous papers.

Along with these advantages, another, in the form of a definite reduction in the incidence of postoperative pulmonary complications following its use, is gradually being established. The figures that follow further substantiate this tendency.

This does not mean that the anesthetic is regarded as the sole cause of postoperative pneumonia. In fact, the pendulum has swung so far that now some authorities actually maintain, arguing from the fact that pulmonary complication follows as frequently after spinal anesthesia, that the anesthetic has nothing at all to do with this complication.

At St. Luke's Hospital we like to think that the anesthetic affects the results directly (1) through the degree of damage or excessive irritation produced in the respiratory tract and (2) through the degree of bodily depression produced by the anesthetic itself⁸ (against that produced by the surgical measures) because of excessive relaxation and prolonged action. Whatever belief may be held regarding the cause of postoperative pulmonary complications, it is obvious that the irritated, mucus-laden respiratory tract is more likely to produce obstruction and atelectasis⁹ than the unobstructed tract.

Judged merely from these two points, without recourse to statistical material, the advantage of cyclopropane over ether for depth of anesthesia sufficient for abdominal operation is obvious.

The direct effect of the anesthetic has been increasingly overshadowed in recent years by other factors, which, in the aggregate, probably do have a more important influence on results than the anesthetic itself. The factors concerned in the production of postoperative pulmonary complications are (1) the anesthetic agent, including the technic of administration and recovery, (2) the site of the operative procedure, (3) the duration of the operation, (4) sex, (5) the preoperative condition of the patient, including age, and (6) the depth of anesthesia. Contemplation of this list shows how broad the problem is, involving many aspects of anesthesia and surgery.

The way selected to present my statistical material on cyclopropane has been to correlate the observations with these six factors. This is the reverse of the usual procedure, which is to study the statistics and emerge with the conclusion that the foregoing six factors are important in the production of postoperative pulmonary complications. What is attempted here is to correlate the specific properties of this anesthetic, through the factors mentioned, to the problem under consideration.

THE AGENT

In the twenty-five month period ended Aug. 1, 1937, cyclopropane anesthetic had been administered 1,333 times in my own practice, in cases which were subsequently observed and studied. Thirteen complications developed, to make an incidence of 0.97 per cent.

Waters, Bennett and Taylor¹⁰ reported an incidence of 0.95 per cent after 5,889 administrations

Several reports on postoperative complications following cyclopropane anesthesia have been gathered and are summarized in table 1. The results are compared to those following the use of older anesthetics, chiefly nitrous oxide-ether. The comparison, with an occasional exception, is favorable to cyclopropane.

This statistical table is considered important to this paper and warrants further comment about postoperative complication statistics in general.

One observation often made is that the more exacting a study becomes the higher the incidence is found to be. For instance, King¹¹ found at the Massachusetts General Hospital in the first year of his extensive studies that, amazingly enough, only 44 per cent of the pulmonary complications actually present found their way to the discharge sheet (from which most perma-

given institution the higher the figures become, and Cleveland¹⁴ showed that as the figures become higher in each succeeding year the incidence of obscure postoperative "reactions" diminishes.

Therefore, with occasional exceptions, the incidence after ether is so much higher than after cyclopropane that it raises the question of the accuracy of record keeping in the cases in which cyclopropane is used. This criticism, however, does not hold. The chief source of mass statistics on cyclopropane is the University of Wisconsin. The methods of record keeping there have been explained in detail¹⁵ and are unsurpassed anywhere. The other data given in table 1 were compiled from a small number of cases, with the resulting likelihood of minimizing error. Furthermore, if the report from this institution possesses any merit, one reason should be that the idea of reporting the results of pulmonary complications was considered

nent hospital records are compiled) His over-all incidence after correction ranged from 3.7 per cent in 1929 to 6.8 per cent in 1931. Against these figures, in another report from a nearby hospital the incidence was found to be only 0.56 per cent. The difference for abdominal operations alone in these two reports was even greater. Possibly the later figures were made from the record room figures alone.

Whipple¹² reported somewhat the same experience as did King. At the Presbyterian Hospital in 1914 and 1915, when no special study of pulmonary complications was in progress, forty-one cases were uncovered. In the following two years, during a special study, ninety-one cases were found. His over-all incidence was found to be 2.6 per cent. One year later, the special study being continued, it was 3.3 per cent (Cleveland). Ehason and McLaughlin¹³ stated that each succeeding year the study is carried on in a

even before the first administration of the new anesthetic was performed, and subsequent observations were made with that intention in view. Personal records and observations have here also increased the number of complications uncovered over those reported on the discharge sheet.

Ether was required to fortify the action of cyclopropane in many cases, particularly during the early months. The decrease in the amount of ether used has been steady. The increase in pulmonary morbidity resulting from the addition of ether is shown in table 2.

As surgeons become more familiar with operating with the patient under cyclopropane anesthesia less ether is requested. One great advantage (from the basis of pulmonary morbidity) of cyclopropane is that when it is used muscles do not completely lose their tone. Respirations are so quiet however, that "pushing" in the abdominal field causes little trouble except at the beginning before pads are placed. Unfortunately, any trouble at the beginning usually causes the surgeon

to request ether immediately. Forbearance for the first two or three minutes will usually allow considerable diminution in the amount or, frequently, the entire elimination of ether. The advantage of this lies in the quicker elimination of the anesthetic (hypoventilation consideration) and the reduction of irritation in the respiratory tract (obstruction consideration).

The technic of administration has been chiefly that of continuous flow,¹⁰ with absorption of carbon dioxide. Waters in numerous papers has established the value of the absorber.¹ The advantages of a controlled and conditioned atmosphere with minimal heat loss and shock has a distinct bearing on pulmonary complication.

The continuous flow method of administration affects results only through preserving a higher percentage of inert gas (nitrogen) in the respired mixture by the use of a partially distended bag instead of a full one. Recently the routine technic of administration used at St Luke's has involved the regular addition of inert gas, chiefly helium, to the anesthetic mixture. This problem, the relationship of nitrogen and other inert gases to pulmonary complications, has been extensively discussed elsewhere by Jones and me.¹⁸

Features of the recovery period emphasized include the immediate placing of the patient on his side on the stretcher and in bed. The matter of position has been stressed recently at the Mayo Clinic¹⁹ among other places, where the Trendelenburg position has been used postoperatively to increase drainage of the pulmonary tract as well as to expedite venous return from the legs. Here at St Luke's the side position is preferred as a better one for drainage, freedom for coughing and vomiting. Venous return from the legs is aided by the necessary motion required of the patient (actively and passively) in getting into and out of the position. The exact position has recently been described by Dill.²⁰ We have used it for eight years and copied it in the beginning from an anesthetist who had already used it many years.

Emphasis is also placed on the anesthetist accompanying the unconscious patient on the return to his

TABLE 2—Postoperative Morbidity Following Cyclopropane Anesthesia With and Without Ether as a Supplement (From January 1936 to July 1937 Inclusive)

| Classification | Cases | Complications | Per centage |
|---------------------------------------|-------|---------------|-------------|
| All abdominal operations | 517 | 11 | 2.12 |
| Abdominal operations—ether supplement | 303 | 9 | 2.97 |
| Abdominal operations—no supplement | 214 | 2 | 0.93 |

Note: No ether was used when the operation was not abdominal except in five cases of hemorrhoidectomy in which it was given for the purpose of prolonging the relaxation of the sphincter muscle and in one other case under special circumstances.

room. One life, beyond any reasonable doubt, has been saved by this routine procedure.

Carbon dioxide by direct addition is not used. A mild hyperpnea during the latter part of the operation, utilizing the patient's own carbon dioxide by means of an open end extension to the respiratory tract, is usually produced.

THE SITE OF OPERATIVE PROCEDURE

In this series 626 of the 1,333 operations either were abdominal or otherwise involved the peritoneum (operations for inguinal and femoral hernias and kidney operations). The entire thirteen complications developed in these cases.

There was no complication in 707 cases of extra-abdominal operation. In our experience the problem of pulmonary complication following inhalation anesthesia for operations not on the abdomen has always been negligible. However, we do a minimal number

TABLE 3—Comparison Between Individual Operations Done with Cyclopropane and Those Done with Other Anesthetics

| Cases | Pulmonary Complications | | Mortality Percentage of Morbidity |
|---|-------------------------|-------------|-----------------------------------|
| | Number | Per centage | |
| Stomach (pre-ent. series cyclopropane) | 23 | 5 | 21.7 |
| Stomach (ward series no cyclopropane) | 291 | 26 | 8.9 |
| Gallbladder and ducts (cyclopropane) | 88 | 3 | 3.4 |
| Gallbladder and ducts (ward series no cyclopropane) | 487 | 90 | 4.1 |
| Inguinal hernia (cyclopropane) | 61 | 0 | 0 |
| Inguinal hernia (ward series no cyclopropane) | 927 | 74 | 3.6 |

of intracranial operations, which are considered to carry a high pulmonary morbidity.¹⁰

The main factor to which is attributed the high incidence of pulmonary complications following abdominal operations is the decreased ventilation and vital capacity of the lungs²¹ subsequent to opening the peritoneum, together with the voluntary restriction of respirations because of pain subsequent to peritoneal irritation. In this regard the value of the technic of administration now used at St Luke's Hospital¹³ requiring the addition of inert gas to the anesthetic mixture and thus prolonging the absorption time of the gases in the hypoventilated or even completely static portions of the lung, is evident.

The other important point associated with the abdominal site of operation as a producer of postoperative complications is the increased depth of anesthesia that necessarily accompanies operations in this area. This will be discussed under depth of anesthesia.

For different types of abdominal operations the incidence of complications varies interestingly. Data on this phase, together with comparisons of results for specific operations from wards where cyclopropane is not used, are given in table 3. The facts are discussed later.

DURATION OF OPERATION

The extreme importance of the duration of the operation has received insufficient attention. All persons concerned with the problem of postoperative pulmonary complications might well become familiar with the figures of Waters, Bennett and Taylor¹⁰ (table 10 of their paper). These, based on 12,349 cases, show the incidence to increase from 2.9 per cent (all complications, major and minor) for an operation of one-half hour, through decided successive stages for each half hour the operation is prolonged, to 30 per cent for operations lasting from three hours to three and one-half hours. These figures

show a continuation of the tendency established a year earlier, reported by Rovenstine and Taylor¹⁵ Their figures showed the incidence for operations lasting one and one-half hours to be double that for operations lasting one hour At two hours the incidence tripled that at one hour

Evidently the pendulum has swung too far to the other side, away from the incision of "an inch and a half in a minute and a half"

In the present series, the average duration of anesthesia in the thirteen cases in which complications developed was one hour and thirty-eight minutes In only one of the thirteen cases did complications develop after an operation lasting less than one hour This fact was outstanding Together with the high incidence of complications following prolonged operations on the stomach, reported in table 3, it caused us to inquire whether the incidence of morbidity is not unduly increased with cyclopropane anesthesia in operations of a prolonged nature, at least over the otherwise very low incidence for this anesthetic The average duration of anesthesia in the five cases in which complications developed after operations on the stomach was two hours and one minute, while morbidity for the entire group of operations on the stomach was 217 per cent

SEX

Mark Twain might better have said of sex, at least in relation to anesthesia, what he said of the weather, that "everybody talks about it but nobody does anything about it" A suggestion is here advanced for doing something about it

Eliason and McLaughlin,¹³ King,¹¹ Brock-- and others have written of the greater incidence of complications for males than for females Eliason and McLaughlin showed that 70 per cent of their cases occurred in males King found complications twice as frequently in males Brock reported sixty-two of eighty-five cases in males

It is unquestioned that males show a greater predisposition to pulmonary complications after anesthesia The approximate figure is more than two to one King went further to say that sex, with the site of operation, is the most important predisposing factor to postoperative pulmonary complications

It is also unquestioned that the administration of anesthetics to males is more difficult than to females Difficulty of induction has been shown by Guedel²³ to result largely from an elevation of the metabolic rate The metabolic rate represents the degree of reflex irritability and oxygen want It represents a fair approximation of the depth of anesthesia that must be traversed before the stable planes of third stage anesthesia (Guedel classification) are reached The difficulty of induction disappears as the metabolic rate is brought down The greater the depth to be traversed the greater is the likelihood of an uneven, struggling induction

In the first place, metabolism in male tissue is the more active, producing on the average 40 calories per square meter body surface per hour, to 37 calories for female tissue Furthermore, muscular action, once initiated, is much more intense in males This results in subsequent derangement in the anesthetic atmosphere through losses and subsequent additions of the anes-

thetic, usually, influenced by the behavior of the patient, in too high concentration This in turn leads to an uneven, irregular induction, a process which, in its optimal form, should be a smooth progression both of succeeding stages in the depth of anesthesia and of increasing concentrations of the anesthetic in the respired atmosphere

In practice the difficulty of induction of a premedicated male is about equal to that accompanying the induction of an unpremedicated female A heavily (properly) premedicated male is looked on as no more difficult than the average female The unpremedicated male there is no excuse for

What I propose to do about sex then is to (1) increase the preliminary medication of males enough to bring them to the operating room almost asleep, with metabolic rates greatly depressed, and as nearly as possible insusceptible to the stimuli of their surroundings, the medication being given far enough ahead (for instance, one and one-half hours for morphine) to have reached its maximum effect before the anesthesia is started and to be wearing off as the anesthesia progresses, and (2) to use cyclopropane, the rapid induction of which, when desired, takes effect with a minimal amount of stimulation, muscular activity and subsequent metabolic elevation

This may be a too didactic treatment of the controversial subject of heavy preliminary medication, the argument against which I have chosen to avoid

In this series seven males and six females had pulmonary complications The total number of females operated on was greater than that of males, but the incidence of complications in males was still nothing like 2 to 1 Nor has universal acceptance of heavy preliminary medication for males as yet been achieved

PREOPERATIVE CONDITION OF THE PATIENT

It has long been observed that elderly, debilitated, septic or acutely ill patients are more prone to postoperative complications Waters, Bennett and Taylor¹⁰ have recently given statistical evidence on this point They showed that a preoperative estimate of the patient as a risk checked closely with the postoperative development of complications

In this series, however, no marked confirmation of these facts was obtained No routine preoperative estimate of all patients was made Five of the thirteen patients who had complications were found to be good risks, and only two exceeded 50 years of age These observations call further attention to the possibility that pulmonary complications after cyclopropane anesthesia depend on other factors, such as physical differences in the anesthesia atmosphere,¹⁸ rather than on the routine ones so clearly established for other anesthetics

DEPTH OF ANESTHESIA

On the important subject depth of anesthesia, surgeons and anesthetists sometimes disagree

The only statistical information available (again from Waters, Bennett and Taylor¹⁰) shows complete confirmation of the long held belief that pulmonary complications increase as the depth of the anesthesia increases

The value of relaxed abdominal muscles and quiet respirations is obvious to all concerned It should be more generally appreciated, however, that increase of the former through deeper anesthesia does not produce the latter Increased depth produces intercostal paralysis and marked diaphragmatic excursions, with

22 Brock R C Postoperative Chest Complications A Clinical Study Guy's Hosp Rep S6 191 (Jan April) 1936
23 Guedel A E Anesthesia A Teaching Outline Preparation of the Patient and Mechanism of Varying Anesthesia Requirements Anesth & Analg 15 157 (July Aug) 1936

resulting increased motion of the abdominal contents. This problem lately has been approached from another angle, with some success.²⁴ Apneic periods are deliberately produced and maintained by artificial respirations, with marked reduction in abdominal motion.

The implications of deep anesthesia are broad and should be generally understood and carefully weighed. Guedel²⁵ stated that relaxed vascular (smooth muscle) tone accompanies marked loss of skeletal muscle tone from anesthesia paralysis. This results in impaired circulation and a tendency to shock. He estimated that to carry a patient fifteen minutes in lower third plane anesthesia is more depressing than to carry him two hours in the first plane.

Henderson⁸ called attention to the loss of tonus, with resulting venous stasis and diminished return of blood to the heart, that accompanies deep anesthesia. Actual measurements of intramuscular pressure, which is con-

One outstanding difference (among others not directly related) in the conditions surrounding these two groups is the increased depth of anesthesia necessary for abdominal work. In this series at least eleven of the thirteen patients with complications were brought to deep third stage anesthesia during the course of the operation.

Until recently the value of an anesthetist was determined by his ability to produce and maintain deep anesthesia. Considerably more thought is now being given to this factor and its relationship to the expansive problem of postoperative pulmonary complications, as outlined here, especially in the light of results following cyclopropane anesthesia. The great advantage of cyclopropane is that it produces a certain degree of muscular relaxation which only rarely can be exceeded. This property has in some instances initiated a tolerance for incomplete relaxation where it did not exist pre-

TABLE 4—Summary of Thirteen Cases in Which Complications Developed

| Diagnosis | Age | Sex | Pulmonary Complication | Day of Onset | Minutes of Anesthesia | Result and Miscellaneous Information |
|---|-----|-----|----------------------------------|------------------|-----------------------|--|
| Appendectomy acute appendicitis | 26 | F | Atelectasis (slight) | Day of operation | 60 | Lungs clear forty eight hours cured |
| Polya's resection of stomach | 40 | M | Atelectasis (severe) | Day of operation | 140 | Lungs clear forty eight hours cured |
| Cholecystectomy exploration of common duct | 48 | M | Embolie pneumonia | 13 | 70 | Cured sudden onset with hemoptysis |
| Second operation fifth day after spinal anesthesia for Polya's resection of stomach intestinal obstruction freeing adhesions of stomach | 40 | F | Embolie pneumonia | 16 | 70 | Cured patient out of bed at onset of pulmonary symptoms |
| Appendectomy acute appendicitis | 43 | M | Broncho pneumonia | 1 | 82 | Cured acute pharyngitis and chest rales preoperatively |
| Resection of stomach | 50 | M | Broncho pneumonia or atelectasis | 3 | 170 | Improved long stormy postoperative course with indefinite chest signs and x-ray appearances |
| Appendectomy acute appendicitis | 39 | M | Broncho pneumonia | 8 | 78 | Cured |
| Hysterectomy appendectomy | 40 | F | Broncho pneumonia | 1 | 135 | Cured long difficult hysterectomy plus injury to bladder |
| Cholecystectomy | 50 | F | Pneumonia | 5 | 90 | Cured postoperative course marked by phlebitis and infection of wound |
| Hysterectomy salpingo oophorectomy | 36 | F | Pneumonia | 6 | 90 | Cured phlebitis developed on the fourteenth postoperative day second pneumonia right apex eighteenth postoperative day |
| Polya's resection of stomach bleeding ulcer | 46 | M | Pneumonia | 3 | 96 | Died ninth postoperative day hemoglobin from 32 to 45 per cent |
| Resection of stomach bleeding ulcer | 38 | M | Pneumonia? | 2 | 120 | Died seventh postoperative day diagnosis of pneumonia not established no x-ray examination continuous vomiting |
| Cholecystectomy | 60 | F | Atelectasis | 1 | 45 | Lungs clear in three days good recovery |

cerned with venous return, have been recorded.²⁶ The readings showed a decrease from 73 mm (average) of water before operation to 48 mm (average) after anesthesia and operation. It can readily be seen that this and the preceding factor together form a vicious circle and hasten shock. Henderson⁸ further stated "The respiratory center exerts at times a dominating control not only over respiratory muscles but over the entire musculature. Profound anesthesia may stop respirations and abolish tonus. The demand of the surgeon for extreme relaxation increases the tendency to serious postoperative sequelae."

With regard to depth of anesthesia, the contrast between the incidence of pulmonary complications developing after abdominal operations and after non-abdominal operations in this series is interesting. 626 abdominal operations, 2.07 per cent, and 707 non-abdominal operations, none.

viously. If this tendency receives further impetus it will have the backing of the sound arguments of physiology.

ADDITIONAL FACTORS

A few matters not included under the preceding six headings remain to be discussed.

Table 4 shows a summary of the facts on which this study is based. The column "Miscellaneous Information" shows that possibly one or two of the cases might have been omitted. On the other hand, another case, in which the complication was undiagnosed for many months after its occurrence and ran its entire course of alarming symptoms in the operating room within twenty-five minutes of the operation, the patient showing no pulmonary morbidity on return to his room, was not included. This case has been reported elsewhere.¹⁸ Two cases of sudden death (sixth and eighth postoperative days) were treated as vascular accidents. A case of mediastinitis subsequent to a traumatic accident accompanying endotracheal intubation with the patient under tribromethanol-cyclopropane-ether anesthesia was not included.

An interesting observation in connection with this table is the low mortality in relation to postoperative

pulmonary morbidity Only two of the thirteen patients died, the mortality thus being 15.4 per cent of the morbidity Other figures run from 20.3 (King, lowest year) to 32.5 (Eliason) and 33.3 (King, highest year) per cent

Data on the postoperative deaths occurring in this series during the first twenty-three months is given in table 5 No death was attributed to the anesthesia One death occurred on the table because of shock and massive hemorrhage

The Council on Pharmacy and Chemistry of the American Medical Association gave great weight to information on deaths in its report²⁷ on cyclopropane, withholding official recommendation chiefly because a series of 2,200 cases of Waters and Schmidt showed a mortality rate of 4.19 per cent compared to a rate of 3.99 per cent for other inhalation anesthetics²⁸ To others this information might seem less important, since a high mortality figure results, among other things, from such uncontrollable factors as the number of patients with inoperable or borderline carcinoma who are encountered and the number of days an appendix has been inflamed before the patient comes to operation

In another paper Jones and I²⁶ showed the slight but definite possibility of a sudden respiratory death

TABLE 5—Data on Deaths Following the Administration of Cyclopropane

following administration of cyclopropane (because of massive collapse of an entire lung) Three cases with autopsy gathered from various sources were reported This rare occurrence should be considered in any discussion of the pulmonary complications following cyclopropane anesthesia

SUMMARY

In an attempt to correlate the statistical material resulting from a study of 1,333 administrations of cyclopropane to the problem of postoperative pulmonary morbidity, the latter was shown to be a broad one involving many factors in anesthesia and in surgery Over some of these factors more control may exist than is at present being generally utilized

The outstanding observation is the relatively low figure both for the incidence of pulmonary morbidity and for the morbidity-mortality ratio following cyclopropane anesthesia This continues the trend established by others in previous reports

MASSIVE ATELECTASIS FOLLOWING CYCLOPROPANE ANESTHESIA

REPORT OF CASES AND A THEORY OF CAUSE AND PREVENTION

OSWALD R. JONES, M.D.

AND

GEORGE EDGAR BURFORD, M.D.

NEW YORK

During the past two years, four deaths following quickly after the administration of cyclopropane have come to our attention Autopsy, when performed showed massive atelectasis of one or both lungs Furthermore, pulmonary complications following long continued cyclopropane anesthesia, especially for operation on the stomach,¹ have increased more than should be expected over the otherwise low incidence of such complications following the administration of cyclopropane²

These facts we regard as sufficient reason for a critical examination of the physical conditions involved in the administration of cyclopropane The relationship of these conditions to the development of massive atelectasis and the greater likelihood of subsequent development of partial atelectasis are considered in detail

In a paper of this nature we feel it necessary to state unequivocally our position on cyclopropane anesthesia

The manner of the introduction of this drug has been a model of careful statement and restraint Even though completely revolutionary in its field, the discovery of the anesthetic properties of cyclopropane by Henderson and Lucas and the subsequent work of Waters and his associates progressed quietly, without any of the publicity and exploitation that have accompanied many lesser events

No one can witness the successful anesthetization of, operation on and subsequent recovery of patients taken directly from oxygen tents without realizing the unique value of cyclopropane anesthesia There are extreme cases to be sure, and far more valuable in the aggregate is the comfort of the large number of patients who receive the benefit of a quiet and pleasant induction The complete disappearance of movement with this anesthesia has prevented many of the bodily derangements due to the lack of oxygen The euphoric action of this gas and its ability to produce mesothoracic deep enough for laparotomy are qualities which add to its importance

With full knowledge of the value of cyclopropane we propose in this paper a suggestion both for avoiding the rare tragedy of massive atelectasis and for reducing the already low figures for postoperative morbidity associated with this type of anesthesia

The circumstance producing complete atelectasis of a whole lobe has of recent years been assumed to be obstruction in the main bronchus followed by absorption of the alveolar gases behind the obstruction When the obstruction has become effective, the time required

From the Department of Anesthesia and the Medical Service of St. Luke's Hospital

for the development of atelectasis depends on the rate of absorption by the lung of the gases distal to the obstruction, provided the circulation in the lung is intact and the alveolar epithelium undamaged.

Coryllos and Birnbaum³ have shown the great variation that exists in the rate of this absorption. The anesthetic gases tested were absorbed in a matter of minutes, as were oxygen and carbon dioxide. The inert gases nitrogen, hydrogen and helium required from eighteen to twenty-six hours for absorption, which even then for helium was not complete.

When one keeps these facts in mind, consideration of the physical conditions surrounding the administration of cyclopropane shows that, with occasional minor failures in technic, the development of massive atelectasis during the actual administration, with or without the presence of the bronchial plug considered so typical of this condition, is at least a possibility.

To develop this idea further, it is plain that, when the mask is placed on the patient's face at the start of cyclopropane anesthesia, the character of the atmosphere being breathed is at first little changed. As the bag fills with cyclopropane and oxygen the resulting mixture changes its physical characteristics in that now a considerably greater proportion of the atmosphere consists of the rapidly absorbable gases that have been added. Nitrogen now comprises considerably less than the normal 79 per cent of the atmosphere.

But during the course of an operation, as a result of various maneuvers, the content of the bag may be partly lost two or three times. Each loss represents a further dilution of the inert gas (nitrogen) content of the bag both by direct loss of nitrogen and by reduction of the remaining percentage through refilling with quickly absorbable oxygen and cyclopropane. Thus with unsatisfactory technic, or as the result of unavoidable losses through other means, the anesthesia atmosphere after a considerable time may be devoid of inert gas except for the small amount of nitrogen brought from the tissues to the lungs by the blood in simple solution and diffused into alveoli. As the blood normally contains about 1 per cent nitrogen, this amount after two hours would probably be very small and its effectiveness in the alveoli accustomed to a nitrogen tension of 80 per cent would be negligible.

The significance of this fact is considerable. Rovenstine and Lemmer⁴ have shown that the time required for a comparable degree of absorption of 600 cc of gas by the lungs of dogs varies as follows: anesthetic and other gases—carbon dioxide one minute six seconds, oxygen one minute twenty-two seconds, nitrogen monoxide one minute forty-two seconds and ethylene two minutes two seconds, inert gases—nitrogen twelve minutes six seconds, hydrogen sixteen minutes twenty-two seconds and helium eighteen minutes six seconds.

Thus they emphasized, as did Coryllos and Birnbaum, the great rapidity of absorption of the anesthetic and active gases as compared with the inert "filler" gases. They observed under direct vision, after blocking the bronchus, that a specific degree of atelectasis appeared after the varying intervals stated for the different gases.

Toward the end of an operation the patient may be breathing an atmosphere made up almost entirely of rapidly absorbable gases, the inert gases having been lost during the anesthesia. When the alveoli of the lungs have lost the supporting properties of the inert gas nitrogen, conditions are present which favor atelectasis.

During an operation the patient's respirations are very quiet because of the preliminary opiates, the cyclopropane and the high oxygen content in the lungs. Together with these factors, which tend to set the stage for a possible collapse of the lung, there is the definite loss of body tonus resulting from the operation itself.⁵ With long-continued shallow respirations, certain parts of the lungs, especially at the periphery, may not be ventilated at all. If, during the period of lack of ventilation, the gases in the resting alveoli consist of only rapidly absorbable oxygen and cyclopropane, it is possible that they may be completely absorbed before further ventilation takes place. Patches of atelectasis may thus develop without an obstruction in any portion of the bronchial tree.

This process, which may be termed creeping atelectasis, could go on, masked by the high oxygen content of the anesthesia atmosphere, until an entire lobe was involved. The first indication of it, beyond possibly an excessive amount of oozing in the operative wound, would appear when the mask was removed at the end of the operation. Then the lack of sufficient working surface of the lung, together with the lowered oxygen content of the inspired air and the increased demands of the body for oxygen on awakening, would soon make itself felt. The patient would show all of the symptoms of respiratory embarrassment, such as marked cyanosis, restlessness and, in some instances, cessation of breathing. The pulse would continue for a time even though the right side of the heart had the added burden of forcing blood through the partially or totally collapsed lungs.

Coryllos and Birnbaum,⁶ in a discussion of this matter in 1932 (before the general introduction of cyclopropane), expressed the opinion that the presence of nitrogen in the air is a fortunate circumstance of nature and that without it general anesthesia would be impossible because of the ease and rapidity of the formation of atelectasis. This was discussed in a theoretical vein. But even then, and for years previous to that time, before the widespread acceptance of the soda lime carbon dioxide absorber⁷ that accompanied the introduction of cyclopropane to medicine, probably the majority of anesthetics were given in an atmosphere seriously lacking in nitrogen. In the now obsolete method of administering gas or gas and ether, a rapid flow of the agent was run through the mask and out into the air in order to carry away the accumulating carbon dioxide. The nitrogen was of course washed out with the carbon dioxide.

Thus physical conditions propitious for immediate development of massive atelectasis without bronchial obstruction in a patient under anesthesia on the operating table have existed for years. Yet to our knowledge only the two cases reported by Bergamini and Shepard⁸

and a questionable one reported by Santee⁹ had come to light before the introduction of cyclopropane. Probably the added factors of quiet respiration and a high alveolar oxygen content have accentuated the possibility with cyclopropane. Actually the blood nitrogen brought to the alveoli and that of the supplemental and residual air are better preserved under the present methods of administering cyclopropane than under most previous methods of handling the older anesthetics.

Coryllos, in another paper,¹⁰ discussed the two cases reported by Bergamini and Shepard. He explained them on the basis of rapid absorption by the lung of the quickly absorbable anesthetic gases plus bronchial obstruction, although the pathologists three years earlier were careful to state that no obstruction was present.

Nevertheless, that a rapid respiratory death from massive atelectasis following the administration of cyclopropane occurs occasionally is beyond question. That pulmonary morbidity after prolonged administration of cyclopropane is unduly greater than the otherwise very low incidence of this complication following cyclopropane anesthesia is suggested by figures from this hospital to be published shortly. The speculation involved, pending further investigation with animals, is whether the process of development follows the outline given here.

The following four cases represent examples of massive atelectasis following cyclopropane anesthesia.

CASE 1¹¹—An ambulatory white woman, aged 31, who weighed 170 pounds (77 Kg), was operated on for subacute pelvic inflammatory disease. Preliminary medication consisted of one-sixth grain (0.01 Gm) of morphine and $\frac{1}{150}$ grain (0.0004 Gm) of atropine one hour before operation preoperatively. The administration of cyclopropane was started at 8:07. Three minutes later the patient was catheterized, and then she was draped for the operation. About eight minutes from the start of anesthesia, before the incision was made, the respirations gradually ceased and the pulse stopped. All attempts at revivification failed, and the patient was pronounced dead at 8:25. Attempts at resuscitation were continued for another half hour.

Autopsy showed bilateral massive collapse of the lungs. The trachea and the bronchi were clear and unobstructed. The right ventricle was dilated, and localized pelvic peritonitis was present.

This case, because of the marked bilateral atelectasis and the careful statement by the pathologist that no obstruction was present in the trachea or the bronchi, fits excellently into the general interpretation we have given to all these cases. However, the onset early in the course of the anesthesia is not typical, and the case differs in this respect from the others.

CASE 2¹²—A man, aged 20, was given cyclopropane by the endotracheal method for an operation on the stomach. The duration of anesthesia was one and one-half hours. The respiration volume was purposely maintained considerably below normal. The patient's condition was excellent at completion of the operation.

On his way back to the ward he showed cyanosis and labored breathing. Oxygen was called for, but the patient was dead within three minutes, before oxygen was made available.

Autopsy showed massive collapse of one lung.

CASE 3^{12a}—A woman, aged 53, of average height and weight and in good physical condition, who was operated on for a

small femoral hernia, was given one-sixth grain (0.01 Gm) of morphine and $\frac{1}{150}$ grain (0.0004 Gm) of atropine about ten minutes before anesthesia started. Anesthesia began at 8:40 and the operation at 8:45, at 9:07 the operation and the anesthesia ended. Both operation and anesthesia were uncomplicated. The patient left the operating room in good condition, but by the time her room was reached she was cyanotic and showed labored breathing. Her condition became rapidly worse. Epinephrine and manual artificial respiration were given without avail. She was pronounced dead at 9:25.

Autopsy showed that the left lung was entirely dark red and noncrepitant. The right lung was aerated but dark red and congested, with patches of atelectasis. The trachea and the bronchi contained a slight amount of mucus but no plugs or obstruction. The right auricle and ventricle were engorged with blood and enlarged to twice their normal size.

Case 4 is our own. It occurred during the early months of our experience with cyclopropane and established a permanently cautious approach toward this anesthetic. No such interpretation as is here given was then attached to the occurrence. It was presumed to be a matter of an overdose, but even then this interpretation did not seem entirely satisfactory to explain what occurred.

CASE 4—Mrs. E. F., aged 35, of average height and weight, was operated on for excision of a rectovestibular fistula. Preliminary medication consisted of one-fifth grain (0.013 Gm) of morphine and $\frac{1}{150}$ grain (0.0004 Gm) of atropine given at 8 a.m. Anesthesia started at 8:45 and ended at 9:33 (duration forty-eight minutes) and was uneventful.

When the mask was removed the pulse rate was 94, the respiratory rate 14 and the color good. The patient was placed on her side on a stretcher and started for her room accompanied by the anesthetist. By the time the elevator was reached, approximately three minutes after removal of the mask, the respirations were shallow and more rapid. Some cyanosis had become evident. The pulse was regular and of good quality. When the patient's floor was reached, respiration had completely stopped and the cyanosis was definite. The pulse was still good. Artificial respiration by a modified Schafer method was begun (the patient was on her side on a narrow stretcher) and the patient rushed back to the operating room. Rapidly flowing oxygen was delivered by tube into the posterior part of the pharynx while manual artificial respiration was being continued and a tightly fitting mask made ready. There was no obstruction to respiration, and a fair tidal volume was maintained by artificial respiration. The pulse remained good for about three minutes after total cessation of the respiration, but during the fourth minute it began to fail and became irregular. Cyanosis by this time was maximal and the patient's condition desperate.

At this point the patient gave an enormous convulsive gasp. This was followed shortly by the resumption of shallow rapid breathing. There was no relief of cyanosis at first despite the breathing by this time of 100 per cent oxygen under efficient artificial respiration. Manual pressure on the bag which had a tightly fitting face piece was used to fortify the now resumed but shallow respirations. The pulse returned to an irregular but more forceful beat shortly after the resumption of spontaneous respiration. During another four minutes the cyanosis cleared somewhat, and in another minute the color was about normal. The patient regained consciousness in ten more minutes. Beyond a slight trace of cyanosis for the first twenty minutes, she had a completely uneventful recovery.

PREVENTION

If our speculation as to the cause of this type of postoperative massive collapse is correct, the obvious remedy is to add inert gas to the cyclopropane mixture. Neff and Stiles¹³ have already suggested the advisability of diluting the cyclopropane atmosphere. They

¹³ Neff W. B. and Stiles J. A. Some Experiences with Cyclopropane Anesthetic with Special Reference to the Diabetic Patient. *Canad. W. A. J.* 5:35-36 (July) 1936.

did not connect the idea of dilution with the prevention of atelectasis but were attempting to prevent the development of shock in operations of three or four hours' duration. They used nitrogen and nitrous oxide as diluents.

For the purpose of preventing atelectasis, the addition of nitrous oxide would serve little purpose, but nitrogen would be effective. Lemmer and Rovenstine have shown nitrous oxide to be absorbed almost as rapidly as oxygen and carbon dioxide.

The most useful addition to the cyclopropane atmosphere or other anesthetic atmospheres should be either hydrogen or helium. Both these gases, besides having more prolonged rates of absorption by the lung than nitrogen, have the added mechanical advantages for respiratory purposes inherent in light gases.

Helium for therapeutic purposes was conceived and introduced into medicine by Barach¹⁴ and has since been adopted for anesthesia by Eversole,¹⁵ among others. Eversole used helium in occasional cases chiefly to overcome spasm of the cords and other forms of respiratory obstruction. Saklad¹⁶ advised its use in the treatment of failing respiration accompanying spinal anesthesia. Hydrogen, the lightest of all gases, may eventually prove to be the most valuable as an anesthetic, particularly if subsequent work confirms or enhances the claimed advantages of very light gases for respiratory purposes.

Helium, however, being light and inert and not explosive, seems at this time to be the best substitute for nitrogen in the replacement of that very necessary supporting gas in the pulmonary alveoli.

In Hershey's¹⁷ experiments with animals, helium with oxygen in percentages of from 80 to 50 supported life as well as normal air over long periods and better than any other gas when mixed with adequate proportions of oxygen.

We therefore suggest the routine use of helium during the administration of cyclopropane or of any other anesthetic given in a high oxygen atmosphere that will tolerate dilution. Helium will not only replace the nitrogen which has been washed out of the alveoli and thus prevent the closure of the alveoli, with subsequent atelectasis but will also bring to the anesthetic atmosphere the mechanical advantage of light gas for respiratory purposes.

The most convenient method for routine use is to establish anesthesia with a small bag content of gases.¹⁸ Approximately enough helium to double the size of the bag is then added. This procedure leaves an adequate oxygen content in the bag. If one assumes that by this time the oxygen content in the bag approximates 60 per cent, the cyclopropane 25 per cent and other gases 15 per cent, then doubling the contents of the bag would leave the oxygen at 30 per cent. But with a low content a considerable amount of other gas and space enters into the calculations. Gas among the soda lime granules, in the face piece and in the supplemental and residual air is to be considered. The supplemental and residual air contains about 2 500 cc. The face piece and canister hold about 1 100 cc. Thus a total space of about

3,600 cc., besides the content of the bag, has to be considered. The individual spaces, while varying in their content of carbon dioxide, nitrogen, oxygen and cyclopropane according to their location, have in common, after the administration of cyclopropane, a higher than normal oxygen content.

Therefore, doubling the size of a "low" bag (containing to begin with about 1½ to 2 liters) is an effective way of supplying a sufficient percentage of helium to the mixture for the purposes suggested in this paper. When helium is used in this way and an allowance made for subsequent additions, the cost is kept low. This averages thus far in our experience about five cents per person anesthetized.

It is well to watch, however, for any sign of cyanosis after these additions. Any additions of helium after the first one should be considerably reduced in amount.

At present the additions of helium used at St. Luke's Hospital are unmetered. If it were desired, the amounts could easily be metered. But too great concern over the accuracy of the amounts added is pretense, as momentary consideration of the unknown and uncontrollable variables will show.

THE IDENTIFICATION OF GONOCOCCI IN COMPLICATIONS OF GONORRHEA

R. J. REITZEL, M.D.

AND

CORDULA KOHL, B.S.

SAN FRANCISCO

As a rule it is not difficult to establish a diagnosis of acute gonorrheal infection, however, the diagnosis of chronic lesions and of complications often remains obscure. The spread of the initial infection to the deeper tissues and to other parts of the body requires dependable and complete bacteriologic studies. Many of the complications of gonorrhea, such as arthritis, gonococcemia and endocarditis, as well as perigenital lesions, have often remained undiagnosed, largely because heretofore little attempt has been made to recover the organism. The reason for failure in diagnosis is twofold: (1) A complication may occur so late that the underlying disease is not suspected and (2) it is a general belief that the gonococcus is difficult to recover and to identify. It is our purpose to illustrate the necessity of making certain of the diagnosis when complications of gonococcal infections are involved and to show that bacteriologic procedures of proved value, which are relatively rapid and simple in performance, are now available for more widespread clinical use.

During the past five years we have recovered the gonococcus from blood, synovial fluid, pus from tendon sheaths, material from cutaneous lesions, peritoneal fluid, fluid from an abdominal cyst, material from ovarian and Bartholin glands and material from labial, periurethral and perianal abscesses. We have in many instances cultured the gonococcus from cervical, urethral or prostatic discharges when examination of smears gave negative or inconclusive results. In fourteen of twenty-five cases of proved gonorrheal arthritis

the history did not indicate previous gonococcal infection, and in these cases either the routine smear was reported to be negative or no urethral or cervical discharge was obtainable. The diagnoses were made by recovering the organisms from blood (in seven cases), synovial fluid (in sixteen cases) or both (in two cases).

ARTHRITIS AND BACTEREMIA WITH SUBSEQUENT RECOVERY

Four patients had arthritis and bacteremia and subsequently recovered. In two of these the invasion of the blood stream appeared to be a transient complication which occurred suddenly in the course of moderately severe arthritis and was characterized by an abrupt rise and return to normal of the temperature. A report of one case is presented.

CASE 1—P. F., a housewife, aged 25, had been admitted to the hospital two years previously for cauterization of the cervix, bilateral salpingectomy, right oophorectomy and appendectomy, after which she became well. The present illness began with chills, fever, nausea and pains generalized throughout the body. When she was admitted to the hospital two days later, the temperature was 100 F and the pulse rate 90. There were

Temperature in case 1

tenderness, pain and slight swelling in the metacarpophalangeal joint of the first digit of the right hand and over the extensor tendons of the dorsal aspects of the left foot and the left knee. After the initial chill a hemorrhagic vesicle developed above the left external malleolus, which two weeks later showed a necrotic center containing pus. Three days afterward vesicles developed on the lateral aspect of both thighs and on the inferior aspect of the right internal malleolus. Two days later a small lesion developed over the left biceps.

On the seventh day after the patient's entry, coincidentally with a sudden rise in temperature to 103.6 F, a large lesion with a necrotic center appeared over the lateral aspect of the right foot, and blood taken at that time for culture showed a growth of gonococci. Within one week the lesion on the foot was 3 cm in diameter, and in its center was a flat pustule 1 cm in diameter, covered with a transparent epidermis which enclosed a small amount of rapidly drying purulent material. The material aspirated from the pustule did not show any organisms in the smear or by culture. The temperature returned to normal on the eighth day and continued so during the remainder of the patient's stay in the hospital, which was uneventful.

The other two attacks of gonococcal arthritis with bacteremia were more severe, however, both patients recovered. One case is of interest because of the difficulty in diagnosis and is presented in brief.

CASE 2—J. G., a married woman aged 52, was well until two days previous to entry, when she got wet while walking in the rain. During the following night she awakened from sleep with severe chills, profuse sweating and generalized pain in all her

limbs. On the following day she complained of pain in her left shoulder and right wrist. Her past history did not show any evidence of previous gonococcal infection. Early in her married life she had had one pregnancy, which had been terminated by abortion. At the time of entry she had known for three years that she had an abdominal tumor. She gave a history of menstrual irregularity and profuse bleeding for the past two years.

On pelvic examination the staff gynecologist found a mass which was considered to be a multilobular leiomyoma of the uterus or possibly an ovarian cyst. A later examination indicated that the patient might have an old adherent tubo-ovarian lesion, but this was not thought to be the focus of her present infection. No vaginal discharge or cervical lesion was present. Smears and cultures of material from the cervix were negative for gonococci. At the time of entry, the patient had a temperature of 102 F and a pulse rate of 90. She had pain in her left shoulder and right wrist and pain and swelling of the left little finger. There were erythematous areas over the surface of the right foot. Five days after entry the left wrist and elbow and both ankles became involved with pain and swelling, and a red swollen fluctuant lesion appeared over the right ulnar surface of the forearm, this lesion, which disappeared after several days, was considered to be possibly metastatic.

On the patient's twenty-first day in the hospital, a blood culture was made, from which gonococci were recovered. On the twenty-eighth day about 3 cc of fluid was aspirated from the right wrist; a smear was not made, but gonococci were recovered by culture. At the time the blood culture was made, pustular cutaneous lesions appeared on the knuckles, the right elbow, one thumb and the soles of the feet. Four days later material from the pustule on the thumb was aspirated and cultured but gonococci were not observed. The patient was given pyrotherapy and recovered.

ENDOCARDITIS, BACTEREMIA AND ARTHRITIS

Gonococcal endocarditis is considered a rare complication. We have been successful in recovering the organism in five cases by culture during life, and in three cases the endocarditis was confirmed at necropsy. We believe that the incidence of gonococcal endocarditis, like that of gonococcal arthritis and gonococcemia, would be found to be greater than is suspected if, in clinical and postmortem studies, greater effort were made to recover the organism. We present a case of endocarditis which was unusual because the diagnosis was made by observing gonococci first in a cutaneous lesion.

CASE 3—S. P., a white man aged 48, became acutely ill with chills, fever and general malaise seven days before entering the hospital. On the second day of his illness a rash appeared on his body and extremities; on the third day several joints became painful, particularly the left wrist, which was swollen. He gave a history of having had gonorrhea at the ages of 16 and 18 but he had had no recent urethritis. Examination showed a maculopapular eruption over the extensor surfaces of the arms, thighs and buttocks and on the left elbow and the left thigh. Individually, the lesions varied considerably in size and in stage of development. There was marked conjunctivitis; there were hemorrhages in the gums on the labial grooves and in the mouth, nose and throat and the tonsils were swollen. The heart showed no abnormalities. The Wassermann reaction of the blood was positive. A small nodular mass was found along the course of the urethra; there was no discharge. The patient had a definite swelling, with redness and tenderness, of the left wrist.

On the day after his entry into the hospital, the left knee became painful. On the third day, a number of bullae appeared in the skin over the buttocks and the ankles; cultures of pus from one of these showed gonococci. These lesions later became pustular, leaving necrotic centers. Cultures of blood taken on the second and the tenth day showed growths of gonococci. The patient rapidly became very ill and almost comatose. His temperature remained between 101 and 103 F and the pulse rate was from 110 to 130. At no time was there any clinical sign of endocarditis and the spleen was not palpable.

The patient was given pyrotherapy, and after the first treatment his condition seemed slightly improved. However, on the thirteenth day in the hospital his temperature rose to 105.4 F, his pulse rate was 120 and his respiratory rate was 52. He expectorated thick, yellowish mucus and perspired freely. During the next day his condition became rapidly worse; his temperature was 105.8 F, his pulse rate 140 and his respiratory rate 40. Rales were present at both bases, and rigidity of the extremities and stiffness of the neck were marked. No murmurs were noted on examination of the heart, and the spleen was not felt. The patient died on the fourteenth day of his stay in the hospital.

Necropsy showed subcutaneous hemorrhages, the bullae in the skin had disappeared, and there were fresh hemorrhages in the abdominal muscles and lungs. There were adhesions around the ascending colon and around the liver. The capsule of the liver was thickened, no cirrhosis was evident and the gallbladder was normal. On gross and microscopic examinations, the urethra and the prostate were found to be normal. The spleen was moderately enlarged. There were no alterations in the myocardium; the mitral valve showed a slight endocarditic patch. There were aortic-verrucous endocarditis and typical acute endocarditis.

It is interesting that of the nine patients with gonococcemia four had cutaneous manifestations. In only one of three attempts were we successful in recovering the organism from cutaneous lesions. Clinically there appears to be a time relationship between the occurrence of bacteremia and the development of cutaneous manifestations. The cutaneous lesions that are discrete and have pustules or necrotic centers are probably metastatic, as was proved in case 3. Klein¹ reported the recovery of gonococci from the cutaneous lesions of a patient with gonococcic arthritis. This is, as far as we know, the only other case reported in the literature in which gonococci were recovered from the cutaneous lesions.

Mention is made here only briefly of the remaining four cases of gonococcic endocarditis, bacteremia and arthritis. In the case of C. M., on examination no evidence was found of gonococcic infection and clinically there was only presumptive evidence of gonococcic arthritis and endocarditis. One week before the patient's death the blood culture showed a growth of gram-negative diplococci which, morphologically and culturally resembled gonococci, although complete identification was not made. At necropsy acute mural endocarditis, with mycotic aneurysm of the left ventricle and secondary involvement of the mitral and aortic valves, was observed. A smear of pus from a mediastinal abscess showed gram-negative diplococci. In the case of L. D., the diagnosis was made from the clinical signs of endocardial involvement, a positive smear of material from the cervix and a positive blood culture; the postmortem diagnosis was diffuse verruciform aortic valvulitis, fibrinous purulent endocarditis, chronic endocervicitis, chronic salpingitis and purulent vaginitis. In the case of R. W., the blood culture was positive simultaneously with the development of clinical signs of endocarditis. No necropsy was made. In the case of S. B., the diagnosis was made by clinical evidence of gonococcic infection and endocarditis, together with repeatedly positive blood cultures.

BACTERIOLOGY

Blood Cultures—In culturing for gonococci, we used hormone-brain broth (hormone-heart-gelatin added to pieces of sterile brain, prepared by the medium depart-

ment of the University of California Hospital). Nearly all pathogenic bacteria can be recovered from blood and other specimens by its use. However, some of the strains of gonococci grew more rapidly in brain-heart infusion (Difco) with the addition of from 30 to 50 per cent of sterile ascitic fluid. Usually both broths were used, 10 cc of blood was inoculated directly into 200 cc of each broth which had been warmed previously. In one instance a specimen was collected into the hormone-brain broth at room temperature, and incubation was not begun for four hours after inoculation. Gonococci were recovered also from specimens of blood collected into 4 cc of sterile 25 per cent sodium citrate solution and brought to the laboratory for inoculation into the mediums. According to our experience, the optimum time for taking the specimen of blood is when the patient's temperature is at the peak of a rise.

Even though examinations of the original cultures were made daily by means of gram smears, the cocci often were not observed until the fourth or fifth day. When about 0.5 cc of the original culture was transplanted after twenty-four hours' incubation to 5 cc of ascitic fluid-infusion broth good growth of gonococci was found in the subculture after only twenty-four hours' incubation.

Synovial Fluid and Other Exudates—The technique for culturing synovial fluid was the same as that used for blood. Gonococci were recovered from two specimens of fluid or pus on swabs which had been kept at room temperature for from fifteen to eighteen hours; the growth seemed to be markedly retarded, however, since it did not appear before the fourth day of incubation. Second specimens from the same patients were inoculated directly, and growth appeared in twenty-four hours. Swab specimens must not be allowed to dry during the interval after they are taken and before the inoculation; placement in an incubator during this interim is entirely contraindicated because of the rapid desiccation. The organisms were seldom observed in the direct smears of the original fluid or pus.

For isolating the gonococcus from discharges containing mixed flora, such as specimens of cervical, urethral or prostatic discharges, pus from perianal abscesses and specimens of urine, the McLeod² oxydase method has proved satisfactory. A brief description of the method is as follows. Inoculation is made on 10 per cent heated blood agar plates; incubation is carried out in a jar containing 8 per cent carbon dioxide for eighteen hours and out of the jar for an additional twenty-four hours. Then the surface of the plate is flooded with a 1 per cent aqueous solution of tetramethyl-paraphenylenediamine hydrochloride, which is allowed to drain off. Colonies having a positive oxydase reaction will turn bright purple within a few seconds; other colonies will become light blue or remain unchanged. Colonies with a positive oxydase reaction which consist of gram-negative cocci and diplococci, are considered to be gonococci. The indicator allows the organisms to remain viable for thirty minutes, so that they may be picked off for further identification whenever this is indicated.

In our modification of the McLeod method, the medium employed is simpler and more adaptable for

¹ Klein, H. M. Studies on the Schwartzman Reaction. Hitherto Undemonstrated Antitoxins in Man. *J. Infect. Dis.* 52: 312-327 (Nov. Dec.) 1933.

² McLeod, J. W., Coates, J. C., Happold, H. C., Priestly, D. P., and Wheatley, B. Cultivation of the Gonococcus as a Method in the Diagnosis of Gonorrhea with Special Reference to the Oxydase Reaction and to the Value of Air Reinforced in Its Carbon Dioxide Content. *J. Path. & Bact.* 39: 221-231 (July) 1934.

use in small laboratories whose facilities do not permit the making of intricate mediums in small quantities. The procedure is as follows: 1. Enough brain-heart infusion (Difco) is added to brain-veal agar (Difco) to make the agar content 12 per cent instead of the usual 15 per cent. This medium is made up in double strength and sterilized in the usual manner. 2. Dehydrated hemoglobin (Difco) is made up in a 2 per cent solution as directed on the bottle and is sterilized. 3. An equal quantity of this heated sterile hemoglobin solution is added to the double strength melted agar, the mixture is then allowed to cool to 50 C., and the plates are poured. The plates should be used on the same day.

Gonococci appear to grow equally well on the two agars with or without the addition of the 8 per cent carbon dioxide. Usually the incubation under the increased carbon dioxide is eliminated, however, the plates are placed in a sealed jar for the first eighteen hours' incubation in order to give the medium an atmosphere which is increased in moisture content. Additional moisture is always kept in the incubator, the temperature for all the cultures for gonococci is maintained at 36.5 C.

Identification of the Gonococci—We relied for identification of the organisms on fermentation reactions and on agglutination with diagnostic serum. The preparation of the medium for the sugar fermentation reactions is as follows: A pure culture of the organisms is inoculated by means of a pipet a broth culture being used, on plates containing sugar-free agar with a hormone base, 30 per cent sterile ascitic fluid, 1 per cent dextrose or maltose and 1 per cent Andrade's indicator. Growth usually appeared in twenty-four hours but fermentation was usually not in evidence before from forty-eight to seventy-two hours. Hiss serum water, which is often used to test fermentation reactions of streptococci and pneumococci, does not give satisfactory results, only one strain out of ten which were inoculated in it produced fermentation, although all gave reactions on the other mediums. These plates were not placed in jars but were incubated in the usual manner.

Agglutination with antigonococcus diagnostic serum confirmed the identification of sixteen strains. Dr. A. P. Krueger, associate professor of bacteriology, University of California, performed the agglutination tests.

SUMMARY

No attempt was made to carry out an intensive clinical or bacteriologic study or to present a complete bibliography. We have presented our results in the culturing of gonococci in gonorrhea and some of its complications such as endocarditis, bacteremia and other metastatic lesions. The bacteriologic procedures that we have outlined aided greatly in diagnosis and therefore were of clinical value in selecting proper therapeutic measures.

3. An excellent bibliography is contained in the Report of the Committee for Survey of Research on the Gonococcus and Gonococcal Infections, prepared by Ruth Doring Thomas and Stanhope Bayne Jones, supplement to the American Journal of Syphilis, Gonorrhea and Venereal Diseases, January, 1936.

Clinical Notes, Suggestions and New Instruments

SERUM CARDITIS, THE MORPHOLOGIC CARDIAC ALTERATIONS IN MAN ASSOCIATED WITH SERUM DISEASE

EUGENE CLARK, M.D., NEW YORK

In a recent report from Bellevue Hospital¹ two instances were described in which patients received large doses of anti-pneumococcus serum and came to necropsy four and nineteen days, respectively, following signs of serum disease. The structural alterations in these cases consisted of proliferation of histiocytes in the mural and valvular endocardium and in the intima of the aorta, pulmonary and coronary arteries, accompanied by multiplication of the interstitial cells of the myocardium and other viscera. Necrotizing arteritis and periarteritis of the smaller coronary arteries was a prominent feature in one case. It was felt that the composite picture is unlike that of any disease heretofore described. The coexistence of these lesions with clinical evidence of serum disease

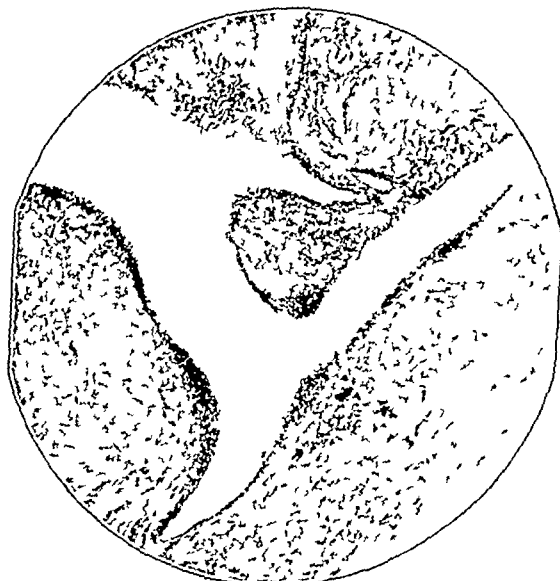

Fig. 1.—Section of the left ventricle showing dense diffuse cellular thickening of the endocardium over the columnar carinae.

and their similarity to those found in animals with protracted anaphylaxis induced by foreign serums, led the authors to suggest that these alterations are of hyperergic nature and related to the administration of foreign serum.

Recently, while studying the visceral lesions of anterior poliomyelitis in the Bellevue Hospital laboratories, Dr. Einar Gustafson² encountered a case from the 1931 epidemic which he called to my attention. This case offers further proof that structural alterations in the heart may accompany serum disease in man.

REPORT OF CASE

R. M., a white youth, aged 20, admitted to the Fourth Medical Division of Bellevue Hospital July 7, 1931, complained of head ache, drowsiness and stiffness of the neck of four days' duration. Physical examination revealed rigidity of the neck, bilateral Kernig sign and incoordination and weakness of the

Store Food and Store Teeth—Let us cease pretending that tooth brushes and tooth paste are any more important than shoe brushes and shoe polish. It is store food which has given us store teeth.—Hooton, E. A. Apes, Men and Morons, New York, G. P. Putnam's Sons, 1937, page 263.

right lower extremity. The temperature was 103 F, the pulse 112 and the blood pressure 114 mm of mercury systolic and 90 diastolic. The spinal fluid showed 180 cells with 76 per cent polymorphonuclear leukocytes and 24 per cent monocytes, culture of the spinal fluid was sterile and the spinal Wassermann reaction was negative.

Soon after admission the patient was apathetic, but in the next few days he became alert. July 11, right external rectus weakness and flaccid paralysis of all limbs more marked on the right were observed. During these four days the patient's temperature did not rise above 101 F and the pulse varied from 90 to 100 per minute. The spinal fluid cell count diminished and the cells were chiefly of the mononuclear type.

July 11, 20 cc of concentrated horse serum was administered intraspinally and an equal amount was given intramuscularly.

During the following week apathy returned, right lower facial weakness developed and breathing became thoracic in type. The temperature rose to 102.6 on the 13th and maintained a level of from 103 to 104 F, with the pulse between 120 and 130. The white blood count July 13 was 16,800 per cubic millimeter with 92 per cent polymorphonuclear leukocytes. July 18 it was 22,400 per cubic millimeter with 84 per cent polymorphonuclear leukocytes, 13 per cent lymphocytes, 2 per cent transitionals and 1 per cent eosinophils. A transfusion of 300 cc of whole blood was given July 14 without reaction. The spinal fluid remained sterile.

July 17 an erythematous rash was noted over the entire body, petechiae over the trunk and arms, edema of the left lid and marked enlargement of the cervical, inguinal and axillary lymph nodes. A blood culture taken at this time was sterile after five days' incubation.

July 18, tympanites and difficulty in respiration were noted. The patient was placed in a respirator. In the following twelve hours the pulse became weaker and irregular. The temperature rose to 107 F, the pulse became impalpable and death occurred July 19.

POSTMORTEM EXAMINATION

Necropsy was performed a few hours after death. Alterations were not observable by naked eye in the thoracic or abdominal viscera. The brain appeared unaltered, but the spinal cord showed congestion, edema and punctate hemorrhages.

Microscopic Changes—Brain and Spinal Cord (described by Dr. Lewis Stevenson). Sections of the medulla, cervical and thoracic cord showed typical lesions of acute anterior poliomyelitis, with marked lymphocytic exudate about the blood vessels and in the substance of the anterior horns. The latter also showed necrosis of nerve cells and a few minute hemorrhages. There was a slight lymphocytic infiltration in the pia arachnoid.

Heart. Paraffin sections of three blocks of tissue removed from the left ventricle were available for study. There were no sections of the valves, larger coronary arteries or aorta.

The myocardial alterations were characterized by dense, diffuse, cellular infiltration and edema of the mural endocardium, particularly over the columnae carneae and the mouths of the thebesian veins (fig 1). The lining endothelial cells were sometimes intact and sometimes invisible but there were no thrombotic deposits or vegetations. The cells were predominantly of the histiocytic type, oval, polyhedral or fusiform, varied in size from 10 to 40 microns and possessed abundant, lightly basophilic cytoplasm. A few lymphocytes and eosinophilic and neutrophilic polymorphonuclear leukocytes were also found. Accompanying this reaction in the endocardium was a focal infiltration of similar cells in the intermuscular connective tissue around the interfascicular arteries, capillaries and venules, between the muscle fibers and beneath the epicardium (fig 2). Though the arteries and arterioles were frequently surrounded by histiocytes the walls of the vessels were unaltered. There were no lesions that resembled Aschoff bodies.

Liver. There was slight focal infiltration of histiocytes in the perilobular areas.

Kidneys. Slight infiltration of histiocytes was visible around some of the glomeruli.

Spleen. There were several foci of hyperplasia in which large mononuclear cells with basophilic cytoplasm predominated.

Lymph Nodes. The architecture of the nodes was preserved but the sinuses were crowded with large mononuclear cells.

Other Organs. The lungs showed edema and congestion. The other viscera were not examined microscopically.

SUMMARY

A youth, aged 20 with acute anterior poliomyelitis affecting all limbs and the muscles of respiration died twelve days after the onset of the disease. Seven days before death, 40 cc of concentrated horse serum was administered. Two days prior to death signs of serum disease appeared. Postmortem study disclosed, in addition to the microscopic appearance of acute anterior poliomyelitis, diffuse infiltration of histiocytes in the subendocardial and connective tissues of the heart accompanied by focal infiltration between the muscle fibers.

COMMENT

According to Landon and Smith,⁴ cardiac lesions of the nature exhibited in the case reported have not been observed in epidemic poliomyelitis. This, fortified by the absence of sepsis, and the similarity of these lesions to those observed in animals during protracted serum anaphylaxis,² and in the two previously reported cases of serum disease in human beings, lead to the

Fig 2—Section of the left ventricle showing cellular infiltration along the intermuscular tracts lining of thebesian veins and between the muscle fibers.

belief that the cardiac alterations in this case are morphologic reactions to horse serum. The existence of serum disease in this patient, as well as in the two patients previously referred to, and the absence of these lesions in those serum-treated individuals in whom serum sickness did not develop,¹ support the suggestion that such alterations represent the morphologic expression of a hyperergic state associated with serum disease. The focal histiocytic infiltration of the liver and kidneys, although milder than in the two other cases, is probably of the same nature.

In the two cases described in the first report, antipneumococcus serum was given several times a day over seven and eleven days respectively, with a corresponding serum volume of 600 and 2,000 cc. The case here reported indicates, however, that this morphologic reaction may follow a single injection (combined intraspinally and intramuscularly) of a relatively small amount of serum (40 cc). The serum employed was concentrated horse serum which may be equivalent to many times its volume of serum refined for its specific immunologic properties.

The structural alterations in the case here reported differ from one of the other two in the absence of necrotizing arteritis.

⁴ Landon J. F. and Smith L. W. Poliomyelitis. New York: Macmillan Company, 1934.

of the coronary arteries. It is not possible to determine the factors responsible for the occurrence of the latter lesion. In the case in which it was observed, death occurred nineteen days after the appearance of serum disease, whereas in the two other cases four and two days, respectively, elapsed between the appearance of serum disease and death.

Cases are too few to permit any conclusion concerning the functional significance of these lesions. In the three cases thus far studied, the underlying disease appears to explain the clinical phenomena and the fatal outcome.

400 East Twenty-Ninth Street

A CASE OF INTESTINAL HETEROPHYDIASIS OF MAN IN HAWAII

JOSEPH E. ALICATA, PH.D.
Parasitologist, University of Hawaii

AND
O. LEE SCHATTENBURG, M.D., HONOLULU, T. H.

Intestinal heterophyid infestation has been reported in man from various parts of the world including China, Japan, Korea, the Philippines, Egypt, and the Balkan states, in areas where parasitized fish is eaten raw or uncooked. Recently a case of heterophyidiasis has been discovered in man in Hawaii, and the source of infestation is believed to have been infested raw fish, possibly mullets, which the patient had eaten. This finding marks a new geographic endemic area for this group of parasites; this new distribution would have been expected because of the large number of Chinese, Japanese, and Filipinos who have migrated to Hawaii, and because of the presence of melanoid snails and mullet, which have been reported in other localities as serving as primary and secondary intermediate hosts respectively of these parasites. It is not surprising also to find human infestation in Hawaii since raw fish is customarily eaten by certain racial groups residing here.

Heterophyid flukes as adults are extremely small, often only about 0.5 mm long. Several species have been reported from man. *Heterophyes heterophyes* was the first member of this group, found by Bilharz in 1851 in the small intestine of a boy in Egypt; since then many other species have been reported from the intestinal tract of carnivorous mammals, birds, and fishes. In 1911 Kutsurata described *Metagonimus yokogawai*, which was the first of these flukes to be found in man in the Orient. Africa and Garcia¹ in 1935 reported the finding of *Monorchotrema taichui*, *Diorchotrema pseudocirrata* (= *Stellantchasmus falcatus*) and *Heterophyes brevicæca* in man in the Philippines; the first two species were also found in dogs.

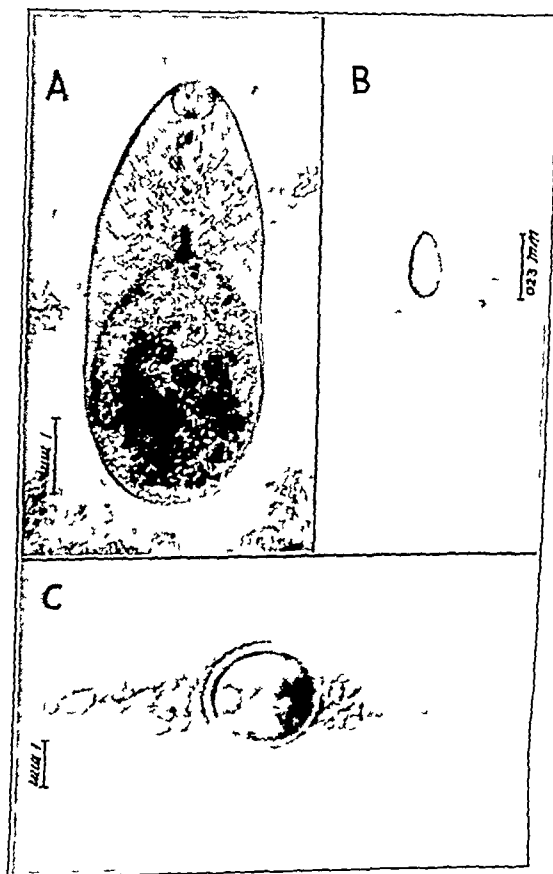

Heterophyids in man have been reported as causing little disorder, and the clinical symptoms due to their presence are often negligible. In 1935 Africa and Garcia² reported that these flukes parasitize the intestinal mucosa and, because of an unbalanced parasitic relationship between the human host and these worms, the latter wander into the deeper layers of the intestinal wall, become unprisoned and die; the ova in the bodies of these flukes that degenerate are taken up by the lymphatic or blood streams and are carried to various parts of the body, including the brain and heart. Africa and his associates² have reported heterophyid ova in acute lesions of the myocardium of several individuals, and these ova were believed to be instrumental in bringing about fatal acute heart attacks; they also suggest that the cardiac beriberi often noted

in the Far East, where the eating of raw fish is common and heterophyid infestations are endemic, are possibly cases of cardiac heterophyidiasis.

REPORT OF CASE

A. N., a man, aged 26, Japanese, was referred to one of us (O. L. S.) June 27, 1937, for diagnosis. The patient was a trainer of polo ponies and worked on a ranch at Mokolei Island of Oahu, T. H. He was born and reared here and never traveled away from the islands. His past history indicated only a severe attack of influenza in 1918, lasting a few weeks, which was followed by a good recovery.

Six weeks before he was seen, diarrhea suddenly developed for which he could not account. When he continued to have from six to ten loose stools daily for several days he consulted a physician but apparently only symptomatic treatment was offered and gave him no relief. The diarrhea persisted for about three weeks during which time he lost his appetite, his body weight dropped from the average level of from 142 to 144 (64.4 to 65.3 Kg) down to 123½ pounds (56 Kg), and he had a corresponding loss in body strength during that time he had shown absence of urinary symptoms, nausea, vomiting, melena and fever. When first seen he was no longer having diarrhea.

A, adult heterophyid *Stellantchasmus falcatus* recovered from the intestine of a cat fourteen days following experimental feeding of an infested mullet; B, egg of the parasite found in the feces of the cat; C, encysted metacercaria of this fluke in the musculature of an infested mullet.

but complained of a nervous feeling and discomfort over the area corresponding to that of the colon and particularly the right upper quadrant. The pain was not acute but was constantly present as a discomfort which was not influenced by the intake of food, evacuation of the bowels or mechanical pressure. Inquiry into his habits brought out the fact that he was a moderate smoker and drank beer occasionally. His hygienic surroundings were good; he lived in a house fitted with modern equipment and his meals included fresh vegetables, milk, eggs and the like. The water supply was from an artesian well on the ranch. He also admitted further being fond of certain kinds of raw fish which he ate with his regular meals.

also when he went into a beer hall for a drink he would frequently eat a "Japanese salad" consisting of raw fish, raw lettuce and soya sauce. He did not know the kind of fish served in the beer halls but at the ranch he ate largely raw 'fresh water mullet and occasionally a local fish which he called 'Chinese cat fish'. He could not date the onset of illness with any particular intake of raw fish.

The patient's physical examination on the first visit was as follows: temperature 98.6° F, pulse, 70, blood pressure, 132 systolic 80 diastolic, weight 123½ pounds. The urine showed only a few scattered pus cells and a few shreds of mucus. A careful physical examination failed to reveal any other noteworthy changes. The clinical impression was that he harbored some intestinal parasite, possibly amebas, and he was advised to enter a hospital for a more thorough study. The following day he entered Queen's Hospital.

Further examination revealed the urine negative, stool negative for amebas, guaiac test negative for occult blood. Blood hemoglobin 75 per cent, red blood cells 4,956,000, white blood cells 9,100, polymorphonuclear leukocytes 47 per cent, eosinophils 2 per cent, small lymphocytes 44 per cent, basophils 7 per cent. The Weil-Felix test for typhus fever gave a negative agglutination in all dilutions. The Widal test gave a negative agglutination in all dilutions for B typhosus, paratyphosus A and paratyphosus B. Undulant fever agglutination was negative in all dilutions. The Wassermann and Kahn reactions were negative. The white blood count July 3 still showed a peculiar shift in the differential: white blood cells 7,100, polymorphonuclears 37 per cent, eosinophils 4 per cent, monocytes 12 per cent, small lymphocytes 47 per cent.

A gastro-intestinal study revealed the following: Fluoroscopy of the chest was negative. Plain plates of the kidney ureter, bladder and gallbladder were negative. A barium sulfate meal showed nothing unusual about the esophagus. The stomach was ptotic. No constant stomach or cap deformities could be found. At six hours there was no delayed emptying of the stomach. At twenty-four hours the colon was partially filled with barium, as was the appendix, which looked normal and was not tender to pressure. A barium enema was negative. X-ray diagnosis was negative, except for some colon irritability.

Studies of the stool were made daily, both from the normal evacuation and after saline purges. The presence of amebas was not found at any time, but small fluke ova from 0.023 to 0.025 mm long by 0.011 mm wide were noted (B in the accompanying illustration). With the finding of these ova he was put on a temporary starvation with purgation followed by 6 Gm of oleoresin of aspidium which was given July 6 in divided doses and with no toxic manifestations. He had several watery stools after treatment, and examination of these stools revealed several hundred tiny flukes about 0.6 mm long by 0.2 mm wide which although partially degenerated, could be identified as belonging to the genus *Stellantchasmus* and closely related if not identical with *Stellantchasmus falcatus* Ouyi and Nishio 1916 (syn *Diorchitrema pseudocirrata* Witenberg, 1929). Following one dose of aspidium the patient began to feel better and was relieved of further symptoms of distress over the colon, his appetite returned and he gained about 3 pounds (1,360 Gm) in the next week. Daily examination of the stool revealed a few ova for two days following the treatment which then disappeared entirely. July 15, when he was discharged from the hospital, the blood count had shown a distinct shift toward normal, being as follows: white blood cells 5,100, polymorphonuclear leukocytes 72 per cent, eosinophils 2 per cent, small lymphocytes 20 per cent, monocytes 6 per cent.

The finding of heterophyid flukes in the patient suggested that local mullet was the carrier of the parasite. Examination of six mullets (*Mugil cephalus*) caught in an enclosed ocean fish pond near Waialua Bay, Oahu, revealed all to be infested with a large number of fluke larvae (metacercariae) encysted in the musculature (C in the illustration). Five additional mullets, caught in the ocean in the Waialua Bay, were also found to be infested, one mullet weighing 265 Gm was so heavily infested that in 1 gram of muscle there were counted

263 larvae. The cysts in the musculature measured about 0.25 mm long by 0.19 mm wide and enclosed a larva partially coiled on itself. Larvae that were dissected from cysts measured about 0.27 mm long by 0.12 mm wide and resembled morphologically the adult flukes recovered from the stool of the aforementioned patient with the exception of size and development of the genitalia. This finding was verified by the feeding of the raw mullet to three young cats. In the course of two days diarrhea developed in all the cats, and on the fourth day one died, at autopsy there were found in the small intestine a large number of heterophyid flukes (*Stellantchasmus falcatus*) about 0.3 mm long with developing ova in the uterus. A daily fecal examination of the other two cats revealed eggs of the flukes passing out on the tenth day following experimental feeding. One of these two cats was killed fourteen days following experimental infestation and a large number of the adult heterophyid flukes (A in the illustration) about 0.55 mm long were recovered from the intestinal tract.

SUMMARY

- 1 This is the first case of heterophyid fluke in man reported from Hawaii and suggests a new endemic focus of the disease.
- 2 The source of the infestation was definitely traced to a species of mullet which abounds in the waters about Hawaii and which is frequently used for food.
- 3 Animal experimentation proved the pathogenicity of this fluke for cats.
- 4 A cure was apparently effected in the human being by the simple use of oleoresin of aspidium.

DUODENAL ULCER AS A CAUSE OF DEATH IN A CASE OF MENINGOCOCCIC MENINGITIS

CARL A. HARTUNG, M.D., CHATTANOOGA, TENN., AND JOSEF WARKANY, M.D., CINCINNATI

Duodenal ulcer in childhood has frequently been described. The literature has been reviewed by Holt¹ by Veeder² and in 1919 by Theile,³ who collected 125 cases. Although additional cases⁴ have been reported since Theile's monograph appeared his classification of the subject can still be considered valid. The majority of ulcers in early life occur in newly born infants suffering from melena neonatorum and in marantic infants. In older children trauma of the gastro-enteric mucous membranes

burns, nephritis, uremia and infections may lead to secondary ulceration of the gastro enteric tract. Ulcers due to infection include those associated with tuberculosis, syphilis, typhoid, pneumonia, smallpox, chickenpox, scarlet fever, diphtheria, measles, erysipelas, pemphigus and appendicitis and the like. Duodenal ulceration has been observed repeatedly with tuberculous and other forms of meningitis. Its occurrence in association with meningococcic meningitis, however, was not recorded in the reviews mentioned, although Eckstein⁶ stated that hemorrhages sometimes take place in the mucous membranes of the intestine in patients with this disease.

Gerdine and Helmholtz⁷ observed diplococci in the base of the ulcer in a large number of children. The organisms were present "in such numbers and in such a position that they presumably are of etiologic significance." In one of their cases there was isolated from the duodenal ulcer *Streptococcus viri-*

REPORT OF CASE

C E, a Negro boy aged 6 years, entered St. Mary's Hospital April 22, 1934, with a temperature of 104.4 F and a complaint of pain in the chest and the abdomen. That night he had convulsions, and on the following day his neck became rigid. Kernig's sign was elicited. Spinal puncture revealed a pressure of 20 mm and a cell count of 5,000 per cubic millimeter. No organisms were seen on direct smear.

The next day the patient was transferred to the Contagious Disease Wards of Cincinnati General Hospital where the following history was obtained. The child had had measles, chickenpox, whooping cough and mumps. He had been vaccinated for smallpox and had received tetanus antitoxin on one occasion. His parents and the two other children of the family, 4 and 8 years of age, were living and well.

On examination the patient who was rational and cooperative appeared moderately ill. He complained of a slight pain in his neck. The respirations were not labored, the rate being about 20 a minute. The temperature was 102.2 F, the pulse rate 40 and the blood pressure 85 systolic and 60 diastolic. There was a fading morbilliform rash on the skin of the abdomen, chest and extremities. The pupils were contracted but equal and regular and reacted to light. The pharynx was slightly injected. The lungs were clear to percussion and auscultation. The heart was not enlarged. A loud, blowing systolic murmur was heard over the entire precordium; the rhythm was regular. No masses were felt in the abdomen and no tenderness was elicited. All physiologic reflexes were absent except the abdominal. Kernig's sign was present. A provisional diagnosis of meningococcic meningitis was made.

Spinal puncture performed April 23, showed a cloudy fluid under a pressure of 18 mm with 6,000 cells per cubic millimeter, of which 98 per cent were polymorphonuclear leukocytes. Direct smear showed no organisms. The following day the culture of the spinal fluid was positive for meningococci. The patient was given intrathecal injections of antimeningococcus serum, from 15 to 30 cc daily, receiving a total of 225 cc over a period of ten days. On several occasions cisternal and spinal punctures were performed simultaneously and irrigation with physiologic solution of sodium chloride was instituted. The patient appeared to be improving. He maintained himself in moderate opisthotonos most of the time. Suddenly on the morning of May 3 he had slight tremors of his entire body. He was given a sedative and later a soapsuds enema which was returned with a large amount of soft slightly formed brown fecal matter. After this his pulse became irregular and barely perceptible. He died two hours after the onset of the generalized bodily tremors.

Necropsy was performed twelve hours after death. In the examination of the gastro enteric tract the esophagus was seen to contain a thick, dark brown fluid with small particles of undigested food. The stomach was distended with thick, brown, bloody fluid. On the posterior wall of the duodenum 5 cm from the pyloric ring there was a deep, crater like ulcer with thick, rolled overhanging edges. This ulcer measured 8 by 12 mm. The surrounding tissues were slightly indurated. The floor of the ulcer was clean and moderately thickened. In the jejunum and the upper half of the ileum thick, sticky, black fecal matter was present. The feces in the colon were slate gray. The Peyer's patches and solitary lymph nodes in both the small intestine and the colon were conspicuous. Those of the ileum just proximal to the ileocecal junction were greatly enlarged and congested. No noteworthy changes were observed in the remaining portions of the gastro enteric tract.

The pancreas was of average size, reddish yellow and quite flabby. Sections through the tail of the pancreas revealed many petechial hemorrhages into the interlobar tissue. In the head of the pancreas these were less conspicuous although the tissue was congested.

The calvarium and the dura were not remarkable. The vessels over the brain were much congested. There were marked flattening of the cerebral convolutions and narrowing of the fissures. The cerebrospinal fluid was slightly cloudy and had a yellowish tinge. Over the base of the brain there was only a faint yellow clouding along some of the blood vessels. There

Fig 1—The duodenal ulcer (X 20)

dans, which on injection into rabbits and dogs localized in the pyloric end of the stomach and there produced hemorrhage and ulceration. The authors concluded, with reference to Rosenow's work with the adult, that duodenal ulcer in childhood may be the result of infection with a streptococcus of particular virulence.

That a meningococcic infection can also result in the formation of a duodenal ulcer may be suggested by consideration of the following case which also appears to be of interest in connection with the neurogenic aspects of the pathogenesis of ulcer.

5 Schmidt W. Das Ulcus rotundum duodeni im ersten Lebensjahr. Berl. klin. Wchnschr. 50: 593, 1913. Gerdine Linton and Helmholtz H. F. Duodenal Ulcer in Infancy. An Infectious Disease. Am. J. Dis. Child. 10: 397 (Dec.) 1915. Berglund.

6 Eckstein Albert. Diseases of the Meninges in Pfandler M. V. and Schlosmann A. Diseases of Children. Philadelphia J. B. Lippincott Company, 1933, vol. 5, p. 56.

7 Cushing Harvey. The Pituitary Body, Hypothalamus and Parasympathetic Nervous System. Springfield, Ill. Charles C. Thomas, Publisher, 1932.

was a small amount of subarachnoid hemorrhage around the medulla. The brain weighed 1,215 Gm. Horizontal section at the level of the basal nuclei revealed no pathologic changes other than moderate edema and congestion. The ependyma was thin, smooth and glistening. The venous sinuses were not remarkable. The vessels of the meninges were congested. There was little purulent exudate around the cord. On section its edges rolled outward. No other pathologic changes were noted.

Sections through the duodenal ulcer, stained with hematoxylin and eosin, showed a rather deep, punched out area disrupting the muscularis mucosae and extending into the longitudinal layer of muscle (fig 1). The duodenal mucosa was practically intact up to the edges of the ulcer. Some necrotic tissue and a rather extensive amount of fibrinous exudate were present in the floor of the ulcer. There was marked invasion of the tissue surrounding the ulcer by various types of cells, mainly polymorphonuclear leukocytes and lymphocytes, with a few endothelial leukocytes. The area of the pancreas adjacent to the floor of the ulcer showed infiltration of the reacting cells along the fibrous septums of this organ. There was moderate edema

Fig 2—Gram negative diplococci having a structure similar to that of the organisms observed in the meninges (oil immersion lens)

of the tissues surrounding the ulcer. Old eroded blood vessels were seen in the section. Sections stained by the Giemsa and the Gram-Weigert method (fig 2) showed definite groups of biscuit-shaped, gram negative diplococci which had a structure similar to that of the organisms observed in the meninges. Numerous other cocci were found, some arranged in short chains, for the most part gram positive.

The pathologic diagnosis was acute and beginning subacute duodenal ulcer with hemorrhage into the intestine, acute purulent meningitis, severe toxic changes in the viscera, multiple abscesses in the kidneys, acute inflammation of the anterior lobe of the pituitary, multiple focal hemorrhages in the pancreatic tissue with subacute inflammation of the pancreatic ducts, acute ulcerative esophagitis, acute splentitis and generalized lymphadenopathy.

SUMMARY

In a boy aged 6 years with meningococcal meningitis who improved under treatment with antimeningococcus serum, a severe hemorrhage occurred from an ulcer of the duodenum and resulted in death on the twelfth day after the onset of the disease.

Sections of the ulcer showed among other organisms groups of biscuit-shaped gram negative diplococci having a structure similar to that of the organisms observed in the meninges.

RECURRENT OR RESIDUAL PROGRESSIVE ILEITIS

GORDON D. OPPENHEIMER, M.D., NEW YORK

In 1932 Ginzburg and Oppenheimer¹ presented their studies of fifty-two cases of nonspecific inflammation of the bowel which had been observed in the previous ten years. An accurate etiologic or pathologic classification of this material was not possible. However, they submitted a classification, "fully conscious of its defects and overlappings but pleading in its favor a certain degree of clinical utility."

One group of fourteen cases presented pathologically a localized chronic nonspecific hypertrophic ulcerative stenosing inflammatory lesion of the terminal ileum, which was sometimes associated with fistula formation. This group, called "regional ileitis," was emphasized in a separate publication with Crohn² because of certain typical additional clinical and radiologic features. In the original communication,^{1a} illustrative cases were cited. One of the cases of ileitis (case 10) has presented an interesting course since the initial radical operation. Since our knowledge of the ultimate outcome of these patients following various methods of treatment is still limited, a detailed report of this particular case seems warranted and follows herewith.

REPORT OF CASE

History—H. C.,³ a man aged 28, Jewish, clerk, admitted to the hospital Jan. 18, 1928, complained of colicky pains in the abdomen unrelated to meals, of three weeks' duration. On the day of admission the pains became more severe and were referred to the right lower quadrant of the abdomen. There had been no vomiting, diarrhea or chills.

On admission, the temperature was 104, pulse 128. The blood count revealed 20,000 white blood cells with 92 per cent polymorphonuclear leukocytes. There was tenderness, rigidity and a mass in the right lower quadrant. Clinically the condition was considered an abscess of the appendix. Laparotomy was performed and a large mass was found in the right iliac fossa. The mass was unraveled and found to consist of cecum, appendix, terminal ileum and its mesentery, and a loop of adherent sigmoid. The appendix was lying in a bed in the mesentery of the terminal ileum. It was about 2 inches thick and was oozing pus. The appendix was removed and the area drained. For the first five postoperative days the patient's course was stormy. The temperature was 107.6 F. on the first day and 105.6 for the next two days but finally fell. The patient was discharged on the twenty-first postoperative day with his wound almost completely healed. The pathologic report of the appendix was acute and chronic inflammation.

Second Admission May 5 to 19, 1931—The patient was well for eight months after the appendectomy. Then the scar broke down in one place and drained a purulent, odorless fluid for two months. Spontaneous healing occurred. For the next year and a half the patient had no symptoms. Two weeks before this admission he began to experience pain at the site of his scar which gradually became more severe. On admission the patient's temperature was 103, and a fluctuant mass presented itself beneath the scar. On incision, about 1 ounce (30 cc.) of thick yellow pus was evacuated. Three days later, fecal drainage was noted. Examination of an injection of iodized oil into the fistula showed that the material entered the cecum and ascending colon. A barium sulfate enema revealed no abnormality of the colon. The patient was discharged with the fecal fistula draining moderately.

Third Admission July 31 to August 5—Physical examination was essentially negative except for the presence of an exudate in the right lower quadrant of the abdomen. It was deemed advisable to continue with conservative therapy and the patient was discharged.

Fourth Admission October 27 to November 22—The interval history was one of moderate loss in weight, occasional febrile

episodes and abdominal pains for the past month. There was no diarrhea. An intestinal fistula was still present.

X-ray studies of the sinus following the injection of iodized oil showed that the bulk of the iodized oil entered the cecum and ascending colon. An exploratory laparotomy revealed that the mass which had been palpated previously consisted of greatly thickened indurated edematous terminal ileum. The fistulous tract led to ileum about 4 cm away from the ileocecal junction. The cecum and ascending colon appeared normal. The ileum was divided 40 cm proximal to the ileocecal junction and about 10 cm above the inflamed area. The ileum and 12 cm of the ascending colon were resected. Both intestinal ends were closed and a side to side, isoperistaltic ileotransverse colonic anastomosis was performed.

The patient made an uneventful convalescence and was discharged feeling well.

Pathologic Examination—The specimen consisted of 40 cm of terminal ileum and 12 cm of ascending colon and attached skin. From the skin a fistulous tract led to a point in the ileum 4 cm from the ileocecal junction. There were some enlarged,

Six hour plate showing stenotic lesion of ileum up to anastomosis

moderately firm lymph nodes at the ileocecal angle. Examination of the interior of the specimen showed that the cecum and colon were normal. Beginning at the ileocecal valve and extending upward for 30 cm there were marked mucosal alterations. The mucosa was congested thickened and thrown up with irregular folds. The rugae had lost their identity. The surface presented numerous hemorrhages erosions and ulcerations interspersed with areas of mucosal hyperplasia. The submucous layers were moderately thickened and fibrotic. Above the inflamed area the ileum appeared moderately dilated but otherwise normal.

Microscopic examination revealed marked mucosal ulceration with chronic and acute purulent inflammation diffuse thickening of all layers of the intestine especially the submucosa due to edema granulation tissue and diffuse infiltration with large and small lymphocytes, plasma cells and occasional polymorphonuclear leukocytes. No tubercles or tubercle bacilli were seen.

The pathologic diagnosis was hypertrophic chronic ulcerative inflammation of the ileum.

Follow-Up—When seen July 3, 1932 the patient felt well. He had gained weight and the bowels moved twice a day. A gastro-intestinal series taken Nov. 14, 1933 showed no significant changes. The patient was seen on numerous occasions and was well until June 1936 when he began to have watery stools and epigastric pain. June 20 another gastro-intestinal x-ray

examination was made. On the four to six hour observations, the distal ileum for a distance of 10 inches proximal to the stoma, appeared to be the site of a marked ulcerative, stenosing lesion as shown in the accompanying illustration.

Fifth Admission, Nov. 5-26, 1936—The interval history five years after resection, was one of occasional attacks of diffuse abdominal pain with three watery bowel movements a day but without pus or blood. The physical examination was essentially negative. The blood Wassermann reaction and urinalysis were negative.

Operation was performed November 7 under spinal anesthesia. The terminal 18 inches of ileum showed the characteristic lesion of ileitis. Its peritoneal surface was dull the wall was thickened inflamed and edematous. Large lymph nodes were present in the mesentery. The ileum was divided proximal to the inflamed area. Both ends were closed and an ileosigmoidal side to side isoperistaltic anastomosis was performed with the upper loop.

Postoperative Course and Follow Up—The patient made an uneventful recovery and was discharged feeling well. He visited the Follow-Up Clinic Jan. 21, 1937, and was found to have gained 7 pounds (3.2 Kg). He was well and asymptomatic. August 4 the patient was working, was feeling well and was having several soft bowel movements daily.

COMMENT

Obviously there are two possibilities to explain the presence of disease after a primary resection. Either it is a true recurrence of a previously uninvolved ileum or the disease was present and unrecognized, following which it persisted and progressed to cause symptoms. Another comparable case has come to my attention from this hospital.^{3a} Jackson⁴ in a recent paper describes a similar case in a woman. His presentation gives perhaps the life history of the disease. When first seen in 1909 the patient was operated on because of pain in the right lower quadrant, vomiting and diarrhea. The preoperative diagnosis was appendicitis but the lesion appeared to be what is now recognized as an ileitis. Nothing but an appendectomy was performed. From then on she had recurrent attacks of abdominal cramps with free intervals. She was operated on in May 1929 (twenty years later) and the lower part of the ileum and the cecum were removed. The lesion was pathologically an ileitis. The patient was free from attacks until five years later when in 1934 severe cramplike pains recurred. A gastro-intestinal series showed a lesion in the distal 30 cm of ileum up to the anastomosis. A third operation (ileocolic resection) was performed in 1935 and the lesion of a recurrent or residual ileitis similar to the original lesion was found. The disease involved only the small intestine, stopping sharply at the anastomosis. Shearer and Jackson⁵ reported a case of ileitis with twice recurrent disease after apparently wide resections.

From these observations it does not seem possible to differentiate between a residual and a recurrent lesion. Even if radical operation had completely removed the disease it is not illogical to suppose that the etiologic factors (which are still unknown) may have persisted and caused the subsequent involvement of the new terminal ileum. On the other hand in favor of a persistent residual lesion with subsequent progression is the possibility that the early lesion of the disease is so minimal that what was considered normal ileum may have already been involved but not evident to the eye or touch.

It might be advisable when doing either a radical excision or the conservative division of ileum with ileocolonic anastomosis to divide the ileum at least 8 to 12 inches proximal to visible or palpable involvement. In addition the operator should examine the ileum carefully far above the lesion looking for inflammation since it is known now that skip or inflamed areas may occur between which lie portions of normal ileum.

941 Park Avenue

3a Since this report was submitted for publication a third patient, a personal one, has returned with vague abdominal cramps and diarrhea. X-ray studies suggest a stenosing lesion of the terminal ileum. The patient was a man aged 29 who was operated on three years ago in this hospital. A wide ileocecal resection was performed for a typical regional ileitis without fistula. As yet a secondary operation has not been done.

Special Article

CHEMICAL ASPECTS OF RIBOFLAVIN

LELA E BOOHER, PH D

WASHINGTON, D C

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. The articles will be published later in book form.—Ed

HISTORICAL SKETCH

The chemical nature of the water-soluble yellow green-fluorescent pigment of whey now referred to as riboflavin (synonymous with lactoflavin, vitamin G and vitamin B₂, as used by many English and German investigators) commanded the attention of chemists¹ as early as 1879. A considerable concentration of this pigment was effected and certain of its more obvious chemical properties were clearly set forth by Bleyer and Kallmann² in 1925. No unusual significance was associated with this pigment by these early workers, who apparently regarded it only as one of the minor constituents of milk, the chemical nature of which was quite obscure.

In 1932 Warburg and Christian³ described a new oxidation enzyme obtained from aqueous extracts of yeast. The enzyme in water solutions was yellow and exhibited a green fluorescence. Together with a second enzyme obtained from yeast and a co-enzyme obtained from the red blood cells of horse blood this "yellow enzyme" constituted an enzyme system capable of oxidizing Robison's hexose-monophosphoric acid ester. The "yellow enzyme" was reversibly reduced to its leukoform during the process. To regenerate the pigmented enzyme it was necessary only to shake the solution carrying it in leukoform with molecular oxygen. In this system the "yellow enzyme," by virtue of its easily reversible oxidation-reduction reactions, acts as an oxygen transport between molecular oxygen and the substrate. It has now been practically established that this "yellow enzyme" is present in every living cell or at least in the cells of all the higher forms of life.⁴

Warburg and Christian³ were able to separate the "yellow enzyme" from yeast and to split it into a protein component and a pigment component. Neither component alone was catalytically active. The separation of these components was effected by addition of three volumes of methyl alcohol to a water solution of the enzyme at a temperature of 38 C, whereupon the protein was denatured leaving the pigment component in solution. These brilliant researches constitute the first separation and identification of the prosthetic or chemically active grouping of an enzyme. Irradiation of

alkaline solutions of the pigment component followed by acidification of the irradiated solution yielded a yellow chloroform soluble photoderivative (later designated lumiflavin). Studies of the chemical nature of this photoderivative which can also be obtained readily from the relatively heat-stable vitamin riboflavin, constituted the crux in the elucidation of the chemical structure of the vitamin and of the prosthetic group of the enzyme.

In 1933 there appeared almost simultaneously from three different laboratories reports supporting a relationship and probable identity of the water-soluble yellow green-fluorescent pigments widely distributed in animal and plant products with vitamin G or vitamin B₂, the accepted chemical name for which is now riboflavin. Ellinger and Koschiar⁵ called attention to the presence of a group of water-soluble yellow green-fluorescent pigments present in milk, liver, kidneys, urine, muscle, yeast and plant materials for which they suggested the name lyochromes, in contradistinction to the group of naturally occurring fat-soluble pigments, lypochromes. These authors suggested also the probable relationship of these pigments to the yellow enzyme discovered by Warburg and Christian. Any one thoroughly familiar with the properties and distribution of the vitamin riboflavin could readily discern from their report the similarity of the qualities of the vitamin with the attributes of the pigments designated as lyochromes.

About the same time I⁶ had succeeded in obtaining from whey powder several concentrated growth-promoting supplements for the Bourquin-Sherman⁷ vitamin G-deficient diet, the vitamin potencies of which paralleled the intensities of yellow pigmentation.

Kuhn and his co-workers⁸ had isolated a water-soluble yellow green-fluorescent pigment from dried egg albumin and reported¹⁰ that the crystalline product was a growth-promoting supplement for the Bourquin-Sherman diet, 100 micrograms a day inducing a growth rate in rats of about 10 Gm a week. In subsequent studies these workers seemingly had difficulty with the Bourquin-Sherman diet and found it necessary to supplement it further with concentrates of unidentified factors present in yeast extracts. These authors also called attention to the similarity in distribution of the vitamin and the water-soluble yellow pigments and to their probable relationship with the yellow enzyme. They suggested the chemical group name of flavins for these pigments, the ending "-in" denoting that they contained nitrogen as an elemental constituent. Since there appeared to be differences in the relative vitamin activities of the yellow pigment preparations, they assumed that there were inherent differences in chemical nature associated with variation in source materials. Pending further chemical investigations they proposed to differentiate them by appropriate prefixes such as ovo-, lacto- and hepato-flavins.

Further investigation has shown that an identical flavin having a d-ribose residue attached to the tricyclic chromophore nucleus (characteristic of all flavins) is

obtained from a variety of natural source materials. Other flavins and flavin derivatives have been synthesized with various groups replacing the d-ribose residue and some of these possess vitamin activity. However, none of these now known possess greater vitamin potency than d-riboflavin and probably all of them are less potent than riboflavin.

The use of the term d-riboflavin or just riboflavin as a substitute for the terms vitamin B₂ or vitamin G was suggested¹¹ by the Council on Pharmacy and

Chemistry. This terminology was later approved by the Committee on Vitamin Standards, American Society of Biological Chemists, and also by the Committee on Vitamin Nomenclature, American Institute of Nutrition (April 1937).

The remainder of the story of the chemistry of riboflavin is the story of the elucidation

of the intimate structure of the molecule, its characteristic properties, its many derivatives and its relation to the "yellow oxidation enzyme."

I Lumiflavin—a predicted partial structural formula

ISOLATION

Riboflavin has been isolated from a wide variety of animal and plant products, including egg white,⁹ milk,¹² liver,¹³ kidney,¹⁴ urine,¹⁵ barley malt,¹⁶ dandelion blossoms,¹⁷ grasses,¹⁸ egg yolk¹⁹ and retinas of fish eyes.²⁰ It cannot be stated with absolute certainty that the crystalline flavin obtained from each of these various sources is chemically identical with riboflavin, but such is the case at least for those to which adequate determinative tests have been applied. Four synthetic flavins closely related chemically to riboflavin have been reported²¹ to possess vitamin activity, but so far none of these have been reported to occur in natural products.

The isolation of riboflavin from these many naturally occurring source materials has been accomplished through the independent efforts of several laboratories. The several methods of isolation employed although slightly diversified in certain detailed manipulations, have much in common. The successive steps in the isolation procedures may be summarized in a general way as follows: (1) extraction of flavin-containing material with aqueous acid solutions, with alcohol or with water-alcohol mixtures, (2) adsorption of the flavin from the extract on fullers' earth, lead sulfide or other suitable adsorbent usually from acid solution, (3) elution of the flavin from the adsorbent by means of pyridine, pyridine-methyl alcohol-water mixtures,

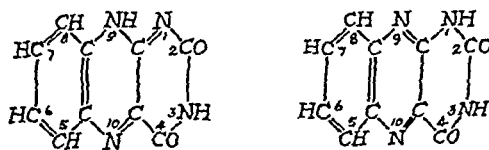

or ammonia in water or in water-alcohol mixtures, (4) removal of elution solvent with recovery and concentration of the flavin in water or alcohol solution followed by elimination of acetone insoluble impurities, (5) precipitation and crystallization of a heavy metal (notably silver or thallium) salt of the flavin which is soluble with difficulty and easily crystallized, and (6) recovery of the metal-free flavin followed by repeated crystallizations from water, alcohol or dilute acetic acid solutions.

In their earlier work, Kuhn and his co-workers⁹ obtained from 100 Kg of dried egg albumin, corresponding to about 33,000 eggs, 100 mg of three recrystallized flavins. According to subsequent measurements²² of the quantities of flavin normally present in dried egg albumin, this yield would correspond to around 7 per cent of the total flavin present in the egg albumin. Similarly the yield of crystalline flavin from milk as reported²³ in the earlier work was not greater than 5 per cent of the total quantity present. The use of heavy metal precipitations increased the yield to around 18 to 20 per cent of the quantity reported²² to be normally present in milk.

Riboflavin crystallizes from absolute alcohol as yellow-orange, needle shaped crystal clusters. The crystals possess no sharp melting point but rather begin to darken at about 240 C and decompose at temperatures of around 274 to 282 C. The tetra-acetyl derivative liquefies with decomposition at about 238 to 242 C. Elementary analysis of the riboflavin crystals established the empirical formula C₁₇H₂₀N₄O₆ corresponding to a molecular weight of 376.

ELUCIDATION OF RIBOFLAVIN STRUCTURE

Following the isolation of riboflavin in crystalline form, the next step directed toward ultimate synthesis of the compound rested on elucidation of its characteristic chemical features. Warburg and Christian⁴ had already isolated a photoderivative from the pigment component of their yellow enzyme and had expounded many of its more salient properties. Exposure of alkaline solutions of the pigment component to ultraviolet irradiation or ordinary light resulted in the formation of a yellow photoderivative (lumiflavin), soluble with difficulty in water but soluble in chloroform and

II Isoalloxazine and alloxazine

having the empirical formula C₁₇H₁₂N₄O₆. The course of this reaction could be followed by acidifying a portion of the solution at intervals and extracting the solution with chloroform. This photoderivative exhibited spectral properties very similar to those of the pigment component of the enzyme having two characteristic absorption bands in the ultraviolet region and one in the visible wavelength range. The yellow color of the photoderivative could be reversibly dispelled by reduction with hydrogen in the presence of palladium. Warming a solution of the photoderivative in the

presence of barium hydroxide liberated urea,¹ thereby disclosing its alkali lability and paving the way for the later disclosure of the presence of an -NH-CO-NH- grouping

The suggestion of a probable relationship of the yellow enzyme and the vitamin riboflavin stimulated no inconsiderable interest in this photoderivative. It was soon found¹² that irradiation of alkaline solutions of riboflavin resulted in the splitting off of a hydroxyl-rich side chain, the latter being responsible for the solubility of the vitamin in water. Since the elementary composition of both the vitamin ($C_{17}H_{20}N_4O_6$) and that of the photoderivative ($C_{13}H_{12}N_4O_2$) had been ascertained, the portion split off must correspond to $C_4H_8O_4$ ($C_{17}H_{20}N_4O_6 - C_{13}H_{12}N_4O_2 = C_4H_8O_4$). Furthermore, acetylation of riboflavin yielded a tetra-acetyl derivative associated with the 4- carbon portion split off by photolysis. One primary alcohol group in the hydroxyl-containing side chain was established from quantitative measurements of the formaldehyde formation resulting from the application of suitable oxidation procedures. The group split off then by photolysis must necessarily correspond to a side chain of the structure -CHOH-CHOH-CHOH-CH₂OH.

Kuhn and Rudy²⁴ made further intensive studies of the products of alkaline hydrolysis of riboflavin and lumiflavin. By heating alkaline solutions of either riboflavin or lumiflavin they obtained urea and an organic acid, $C_{12}H_{12}N_2O_3$,

which contained one active hydrogen atom and which formed a bright yellow silver salt and gave a sharp monobasic acid titration curve. For the splitting off of urea by alkaline hydrolysis of lumiflavin, two molecules of

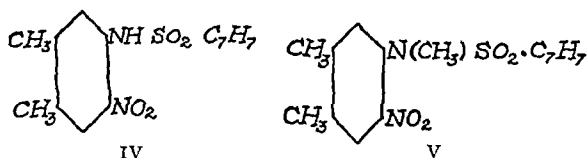

water were required. This would indicate that the urea-yielding group belonged to a ring system and not to a side-chain ureide or guanidino group wherein only one molecule of water would be required. These observations, jointly considered, make it evident that both oxygen atoms of lumiflavin ($C_{13}H_{12}N_4O_2$) belong to an alkylatable ring, one going to form urea and the other to build the carboxyl group in the organic acid $C_{12}H_{12}N_2O_3$.

Further studies²⁵ led to the finding that both lumiflavin and the organic acid $C_{12}H_{12}N_2O_3$ contained an alkylimide grouping, in contrast to riboflavin, in which this grouping is absent. Apparently then the sugar-like side-chain split off by photolysis of riboflavin was replaced by an alkyl group. As a result of the studies of the decomposition products of riboflavin and lumiflavin the partial structural formula I for the latter was advanced by Kuhn.

In the riboflavin molecule a d-ribityl group replaces the methyl group of lumiflavin at position 9. This proposed structure definitely related riboflavin and lumiflavin to the alloazine series of organic compounds, which were first discovered by Kuhling²⁶ in 1891 and which possessed many properties similar to those of flavins.

The structures of alloazine and its tautomeric form, iso-alloazine, are represented in formula II.

Riboflavin and lumiflavin are derivatives of iso-alloazine, since riboflavin and lumiflavin each possess only one active hydrogen atom, namely at position 3, while the alloazine molecule contains two active hydrogen atoms (positions 1 and 3). In riboflavin and lumiflavin the hydrogen attached to the nitrogen at position 9 is replaced by a pentose residue and a methyl group, respectively.

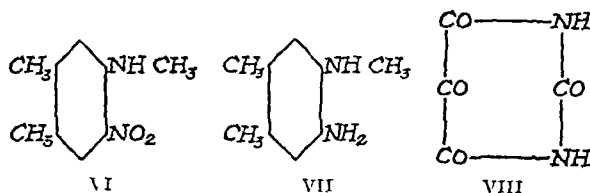

A structural formula III was predicted for riboflavin and subsequently confirmed by synthesis. The formula shows the side-chain as ribose.

It was not known in the early stages of the investigations, of course, that the spacial relationships of the hydroxyl-containing side-chain corresponded specifically to d-ribose.

SYNTHESIS OF LUMIFLAVIN AND RIBOFLAVIN

Once the essential structural features of riboflavin had been deciphered, attempts to synthesize many of its chemically related compounds were quick to follow. The synthesis of lumiflavin was achieved before that of the vitamin. Except for the reaction involving condensation of the 6,7-dimethyl derivative of ortho-phenylenediamine with allozan, a reaction based on the earlier work of Kuhling²⁶ and Kuhling and Kase-litz,²⁷ the steps involved in the synthesis of this compound are well known in the field of organic chemistry.

The synthesis of lumiflavin as developed by Kuhn and his co-workers²⁸ is as follows. Ortho-xylene on treatment with nitric acid yields 1,2-dimethyl-4,5-dinitrobenzene, which on partial reduction yields 1,2-dimethyl-4-nitro-5-aminobenzene. The latter is heated at 100 C with paratoluene sulfone chloride in pyridine for four to five hours and yields a product with formula IV. This intermediate on treatment with dimethyl sulfate and alkali at 50 to 60 C yields a

methyl derivative V. Hydrolysis of this derivative can be accomplished with a mixture of glacial acetic and concentrated sulfuric acids and there is produced the methyl amino compound VI. The nitro group of compound VI is reduced with stannous chloride and hydrochloric acid to yield the amino compound VII. The hydrochloride of compound VII is condensed with a slight excess of allozan VIII in water at 50 to 60 C to yield lumiflavin IX, the yield over all is about 75 per cent.

The alkaline hydrolysis of lumiflavin forms urea and an alkaline salt of the organic acid $C_{12}H_{12}N_2O_3$, X, a reaction of material assistance in elucidating the structure of the tricyclic chromophore nucleus of riboflavin.

Without the presence of the modified pentose side-chain attached to the N-atom position 9 (see proposed structural formula III for riboflavin) the flavin possesses no vitamin activity. Since the grouping $-CHOH-CHOH-CH_2OH$ possesses three asymmetrical

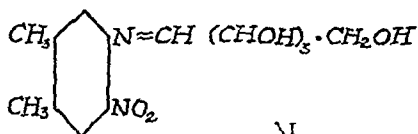

I

II Salt of the acid $C_{12}H_{12}N_2O_3$

carbon atoms, there existed eight theoretically possible stereoisomers of the proposed structure, one of which presumably would be identical to that in natural riboflavin. The possibility was also tenable that more than one configuration would exhibit vitamin activity. The selection of possibilities which might yield a product identical with the naturally occurring vitamin could be somewhat narrowed in view of the optical activity of the vitamin as isolated. The vitamin exhibited optical activity only in alkaline solution, in which case it was levorotatory, and presumably the relative spatial relations of the $-H$ and $-OH$ groups nearest the chromophore group of the vitamin control the sign of rotation. This information narrowed the choice to l-arabinose, d-xylose and d-ribose residues for the hydroxyl-containing side-chain which might be identical with that in the vitamin molecule. The pentyl side-chain corresponding to d-ribose was finally proved to have the same spatial relationships as the side-chain involved in the naturally occurring vitamin. The synthetic d-riboflavin was identical in chemical properties with the vitamin as isolated from various source materials and the mixed melting point (attended with decomposition) of the synthetic and natural products indicated no depression of this constant.

The synthesis of d-riboflavin as developed by Kuhn and his co-workers²⁸ was the same as that for lumi-

XI

flavin to the stage of formation of 1,2-dimethyl-4-nitro-5-amino-benzene. This compound on heating with d-ribose yields compound XI. The latter can be reduced with platinum black to give XII. On treatment with alloxan in a mixture of acetic and boric acids, a condensation occurs with the formation of d-riboflavin III.

Karrer and his co-workers²⁹ meanwhile had also developed a method of synthesis for d-riboflavin and

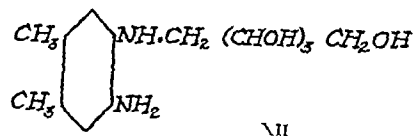

recently³⁰ have described an improved method giving a yield of about 38 per cent of the theoretical yield calculated on the basis of the quantity of d-ribose employed. Starting with 2 Gm of d-ribose they obtained approximately 2 Gm of riboflavin.

The chief obstacle involved in the preparation of the synthetic vitamin riboflavin is the limited availability of the essential d-ribose. The supply of d-ribose used by both Karrer³⁰ and Kuhn²⁸ was prepared from d-arabinose, which in turn was obtained from the calcium salt of d-gluconic acid, a synthesis of five steps summarily attended with considerable losses. Kuhn and his co-workers²⁸ report that from 2 Kg of the calcium salt of d-gluconic acid (yielding about 500 Gm of d-arabinose) they obtained 53 Gm of d-ribose.

The l-araboflavin has been synthesized³¹ and found to possess vitamin activity, but in comparison to d-riboflavin it has been reported³² to be only about one third as potent.

PROPERTIES OF RIBOFLAVIN AND RELATED COMPOUNDS

Syntheses of many derivatives of riboflavin have demonstrated the extremely limited alterations of the structural configuration of the riboflavin molecule compatible with vitamin activity. While the tricyclic chromophore nucleus is common to all flavins, the position and kind of substituent groups on the benzene ring and the nature of the side-chain attached to

XII

the nitrogen atom in position 9 are determinant factors for vitamin activity. The following synthetic flavins have been shown to possess vitamin activity: 6,7-dimethyl-9-[d,l'ribityl]-iso-alloxazine (riboflavin),³³ 6,7-dimethyl-9-[l'arabityl]-iso-alloxazine (araboflavin),^{31a} 7-monomethyl-9-[d,l'ribityl]-iso-alloxazine,²¹ 6-monomethyl-9-[d,l'ribityl]-iso-alloxazine²¹ and 6-ethyl-7-methyl-9-[d,l'ribityl]-iso-alloxazine²¹.

At least one of the methyl groups in position 6 or 7 is essential in order that the flavin molecule shall possess vitamin activity. The absence of both the 6 and 7 methyl groups actually appears to be accompanied with toxicity.²⁴ As regards the side chain, only d-ribose or d-arabinose residues attached to the nitrogen atom in position 9 have thus far proved to be compatible with vitamin activity of the flavins. Exceedingly small variations in this side-chain are attended with complete lack of vitamin activity.

Fluorescence—One of the most characteristic properties of riboflavin is its yellow green-fluorescence in neutral solutions. The fluorescence is at a maximum in the region of pH 6.0 to pH 7.0 and decreases in either more acid or more alkaline solutions. This observation would indicate that riboflavin was amphoteric.

teric in nature and that the electrically neutral molecule was responsible for the fluorescence Kuhn and Moruzzi³⁵ made a series of fluorescence measurements of riboflavin solutions with graded p_H values At p_H 1.7, on the acid side, and at p_H 10.2, on the alkaline side, the fluorescence was 50 per cent of its maximum value Using these data in the generally accepted manner for calculation of the dissociation constants of base, acid and iso-electric point they obtained the following values

$$k_{acid} = 63 \times 10^{-12}, k_{base} = 0.5 \times 10^{-12} \text{ and} \\ \text{iso-electric point, } p_H 6.0$$

These authors used ultraviolet rays and were of the opinion that in the region of optimum p_H the fluorescence brightness was proportional to the riboflavin concentration

Later, Karrer and his co-workers³⁶ reported that maximum fluorescence of solutions (p_H 7.0) of riboflavin appeared with concentrations of 0.003 per cent, the fluorescence intensity decreasing with either greater or lesser concentrations They suggest that Kuhn and his co-workers probably used such dilute flavin solutions that the measurements were all made far below the maximum fluorescence brightness

The fluorescence measurements for lumiflavin gave practically the same k_{acid} and k_{base} constants as those for riboflavin, indicating that the sugar-like side-chain of riboflavin has very little influence on the electrolytic properties of the molecule³⁵

The retinas of the eyes of many species of animals have been reported³⁰ to contain relatively high concentrations of flavin, the concentration corresponding rather closely to that at which maximum fluorescence occurs It is supposed that the flavins are involved in some balanced light sensitized reactions concerned with dim vision

Optical Activity—In neutral solutions or in acid solutions wherein the riboflavin exists as a positively charged ion, the optical activity of riboflavin is exceedingly small In nonfluorescent alkaline solutions of riboflavin the maximum rotation (levo-) was observed³⁷ when one mole of riboflavin is in the presence of one mole of sodium hydroxide This maximum rotation was given as $[\alpha]_D^{20} = \frac{-0.51 \times 100}{0.447 \times 1} = -114^\circ$ (in 0.1 N NaOH) Karrer and Fritzsche³⁸ confirm this dependence of specific rotation on the relative concentrations of riboflavin and alkali

Solubility and Stability—Riboflavin, owing to the presence of its d-ribityl side-chain, is a typically water-soluble type of compound and is insoluble in the ordinary fat solvents By splitting off this d-ribityl side-chain the resultant molecule becomes soluble in such solvents as chloroform

Riboflavin is quite stable in strong mineral acids but sensitive to alkali Riboflavin is sensitive to light and on irradiation with ultraviolet rays or visible light undergoes irreversible decomposition Irradiation of alkaline solutions is attended with the formation of lumiflavin, $C_{13}H_{12}N_4O_2$ Irradiation of neutral or acid solutions of riboflavin is attended with the formation

of 6,7-dimethyl-alloxazine, or "lumichrome,"³⁹ which exhibits an intense blue fluorescence

Riboflavin is quite stable to oxidizing agents, including hydrogen peroxide, bromine water and concentrated nitric acid It is oxidized by chromic acid, yielding ammonia, carbon dioxide and a nitrogen-free residue

Riboflavin is reversibly reduced by hydrogen (palladium or platinum and hydrogen, zinc in presence of acid), by sodium thiosulfate and by hydrogen sulfide in alkaline solution and by titanous chloride

Oxidation-Reduction Potential—The very unique as well as complicated oxidation-reduction systems of the flavins have attracted unusual attention and also have caused a considerable volume of literature to be built up

The flavins represent very stable oxidation-reduction systems, imparting quite reproducible potentials to noble metal electrodes within a reasonable range of buffering capacity In relation to molecular structure it has been shown⁴⁰ that acetylation, methylation or loss of the sugar-like side-chain of riboflavin does not materially affect the oxidation-reduction potential of the flavin Titration of the completely reduced flavin with a suitable oxidant (or vice versa) at graded p_H values forms the basis for a series of curves which have been variously reported as corresponding to a one electron system and a two electron system and an intermediate electron system Apparently the electron number shifts and is different at different ranges of p_H values, which would account for some of the divergence in reports According to Stern,⁴¹ the slope of the titration curves in the range of p_H 6.0 to 12.4 corresponds to that of a two electron system From p_H 4.0 to p_H 1.0 the character of the curves is that of a one electron system, while at p_H values of less than one the steepness of the curves gradually increases until at p_H 0.4 two maxima appear, indicating a two-stage process At p_H values less than 5.0 a red intermediate compound, as first noted by Kuhn and his co-workers,⁴² appears, which becomes more pronounced as the two-stage separation is approached at about p_H 0.4

The normal potential of riboflavin referred to the normal hydrogen electrode is in the region of $-0.21V$ (p_H 7.0) as reported by many investigators, including those referred to The physiologic significance of the extremely negative position of the normal potentials of the flavins is not at present understood Under the general anaerobic reduction potential of living cells, the cell flavin is said⁴³ to be exactly in its equilibrium range

In a recent report, Kuhn and Strobel⁴⁴ state that in the conversion of riboflavin to leuco-riboflavin no less than three different reduction intermediates intervene and that these are distinguishable by vivid colors and sharp definite compositions

Absorption of Light by Flavins—Riboflavin, lumiflavin and the yellow enzyme exhibit characteristic absorption bands with well defined maxima in approx-

mately the same wavelength regions. It is apparent, therefore, that this property resides in the tricyclic chromophore nucleus of the flavins. Riboflavin exhibits definite maxima at approximately 220, 267, 366 and 446 millimicrons. The green fluorescence extends from about 500 to 630 millimicrons. The use of the extinction coefficient especially in connection with the wavelength maximum at 267 millimicrons is useful in measuring the relative purity of riboflavin preparations.

Flavin Combination in Natural Products—At least 90 per cent of the riboflavin in milk is in a free dialysable form. In most other materials, such as liver, yeast and green leaves, it occurs in combination with compounds of high molecular weight.⁴⁵

VITAMIN ACTIVITY OF RIBOFLAVIN

No fewer than a dozen reports have appeared which carried some semblance of a quantitative relationship between riboflavin dosage and the growth rate of rats on a riboflavin-deficient diet. In many cases, however, such meager data were supplied in these reports relative to the control of the experimental animals that critical examination of the work is impossible. It would seem probable that no two groups of workers had used

XIII Yellow oxidation enzyme (Warburg)

the same riboflavin-deficient diet and probably most of them had not completely eliminated the practice of coprophagy in the experimental animals. The action of micro-organisms is responsible for the formation of flavin in the lower colon.

Kuhn and his co-workers⁴² have reported that 7 micrograms of riboflavin was equivalent to a Bourquin-Sherman unit when the Bourquin-Sherman Vitamin G-deficient diet⁸ was supplemented with vitamin B₂. In other words, they state that 7 micrograms of pure riboflavin will support a growth rate of 3 Gm a week in standardized rats receiving this modified Bourquin-Sherman diet.

Von Euler and his co-workers,⁴⁶ using a somewhat different diet, report that 2 micrograms of riboflavin correspond to a Bourquin-Sherman unit.

In my experience (unpublished data), 3 micrograms of crystalline riboflavin per rat daily as a supplement to the Bourquin-Sherman diet regularly induced a weekly growth rate of 3.1 ± 1.0 Gm. The practice of coprophagy in these experiments was completely eliminated and the vitamin G-deficient diet was prepared as originally described by Bourquin and Sherman.

The riboflavin requirements are closely related to body size or more particularly to mass of active tissue, a further fact which may help to explain some of the divergence in vitamin values reported for riboflavin.

RELATION OF RIBOFLAVIN TO THE YELLOW ENZYME

The yellow oxidation enzyme discovered by Warburg and Christian has been isolated in crystalline form by Theorell.⁴⁷ This isolation was accomplished by a combination of cataphoresis and fractionation with ammonium sulfate. Cataphoresis was used principally to separate the enzyme from large amounts of polysaccharides, which would interfere with the subsequent fractionation.

The reversible splitting of the protein and riboflavin components of this enzyme was accomplished by dialysis against dilute hydrochloric acid followed by dialysis against water. By mixing the electrolyte-free water solutions of the components in the cold, the activity of the enzyme for the most part returned.⁴

The molecular weight of the enzyme as calculated by Kerwick and Pedersen⁴⁸ from the sedimentation and diffusion data, sedimentation equilibrium data and assuming that the enzyme contains one molecule of riboflavin (molecular weight 376) per molecule of enzyme, gave values in the neighborhood of 80,000. The iso-electric point of the enzyme was found to be about p_H 5.2.

Theorell⁴⁹ furthermore found that riboflavin existed in the enzyme as a phosphoric acid ester, a nucleotide combination in which the purine is replaced by riboflavin. Kuhn and his co-workers⁵⁰ have succeeded in synthesizing the riboflavin-5'-phosphoric acid ester (6,7-dimethyl-9-d-riboflavin-5'-phosphoric acid) and find it identical with cytoflavin from heart muscle. The phosphoric acid radical is, in fact, one of the connecting links between the riboflavin and the protein component of the enzyme. It has been postulated⁵¹ that the protein component of the enzyme is bound to the phosphoric acid radical and to the free imide group in position 3 of the riboflavin-5'-phosphoric acid ester. Riboflavin itself is much less effective than its phosphoric acid ester in combining with the protein component, while a blocking of the hydrogen atom of the imide group in position 3 prevents the combination of protein and flavin components. Kuhn and his co-workers have, as a result of these observations, expressed the combination of protein and riboflavin phosphoric acid ester as shown in formula XIII. A less active enzyme is formed by combination of riboflavin (unesterified) and the protein component solely through the imide grouping of the former at position 3. This combination is broken by dialysis against distilled water at p_H 7.0.

The yellow oxidation enzyme contains 15.9 per cent of protein and 0.043 per cent of phosphorus. It also possesses at least three distinct absorption maxima at wavelengths of 265, 380 and 465 millimicrons. For

further details of the chemical and enzymatic properties of this enzyme the reader is referred to the review by Theorell^{1,2}

The role of riboflavin as a component of an oxidation enzyme present presumably in all living cells explains some of the observations which were so baffling only a few years ago. Animals subsisting on riboflavin-deficient diets for any considerable period were invariably in a more critical condition than outward and obvious signs could indicate. They appeared for quite some time before death to be on the verge of collapse. This condition would seem to be a necessary corollary to the cellular asphyxiation brought about by a lack of a cellular oxidation catalyst.

SUMMARY

Riboflavin (6,7-dimethyl-9- [d-riboityl] -iso-alloxazine) is a yellow green-fluorescent water-soluble pigment widely distributed throughout both the plant and the animal kingdoms.

Through its iso-alloxazine nucleus it is related to and possesses a combination of the chemical properties of a substituted benzene, an azine dye and a pyrimidine. In addition, riboflavin possesses a ribityl side-chain attached to the N-atom in position 9, which relates it to the pentose sugars.

Riboflavin forms a phosphoric acid ester (riboflavin-5'-phosphoric acid) which combines with a protein to yield a yellow oxidation enzyme. This enzyme is presumably present in every living cell, at least in the cells of all higher forms of life, and is concerned with the chemical reactions involved in cell respiration.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORT HOWARD A. CARTER, Secretary

WESTERN ELECTRIC 3-A ELECTRICAL STETHOSCOPE ACCEPTABLE

Manufacturer Western Electric Company, 195 Broadway,
New York

This portable electrical stethoscope is designed to aid the physician in hearing heart sounds and in diagnosing heart ailments. It has been developed particularly for physicians with impaired hearing, according to the firm. However, it is equally recommended as useful to the physician with normal hearing in examining thick chested individuals or detecting heart conditions during their early stages. It is claimed by the firm that other useful applications will be found in obstetric and lung fields.

Readily portable, the instrument is housed in a small fabricoid carrying case, 12½ by 8¾ by 4¾ inches, weighing approximately 14 pounds. This contains the entire equipment, consisting of tubes and electrical wiring, six dry cell batteries and a space containing the microphone receiver and cable. Provision is made for an additional receiver to be connected with the stethoscope so that two physicians may listen to heart sounds from the same patient simultaneously.

The Electrical Stethoscope essentially consists of a sensitive microphone, a vacuum tube amplifier and a receiver to reproduce the sounds. The two-stage amplifier, operated by dry batteries, will increase the loudness of the heart sounds about 20 decibels, or 100 times the intensity obtained with an ordinary acoustical stethoscope. The amplifier has a maximal gain of 60 decibels. Its frequency gain characteristic is essentially flat over a range in excess of that covered by the pick-up. This pick-up is

unresponsive to extraneous sounds and has a frequency range running from 60 to 1,500 cycles, which covers the frequency range of heart sounds, according to the firm. It contains a filter which may be cut in or out of the circuit by means of a switch located on the front of the instrument, accentuating murmur sounds. The filter control diminishes the response at both the low and high frequencies. Thus the intensity of normal heart sounds is lowered and the loudness of any existing murmurs is accentuated by the isolation.

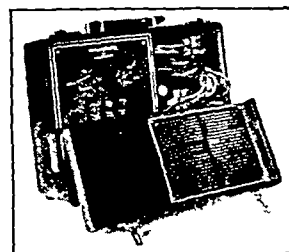

The batteries are stored in the two bottom compartments of the chassis. These are a filament battery, consisting of four flashlight cells No. 950 and two No. 768 plate batteries. The latter are of the plug-in type, with their terminals attached to receptacles mounted in the top of the battery. This simplifies replacement, since the leads used to connect them terminate in polarized plugs, so that they cannot be incorrectly inserted.

Like the pick-up, the telephone type receiver is provided with a special cap to allow attachment of the tubes of an acoustic stethoscope. These tubes modify the quality of the sounds heard and are employed with this instrument instead of headphones so that the sounds heard will be as nearly as possible like those heard with the usual stethoscope.

A single volume control is provided which turns the amplifier off at the extreme left position and gives increased volume when turned to the right. The filter switch is the only other control and is used only when murmurs are suspected.

The unit was investigated in a clinic satisfactory to the Council. It was reported that the instrument distorts in a measure the heart and breath sounds so that a certain amount of experience is necessary to learn the normal sounds as produced by it. It did not appear to bring to light murmurs that are inaudible to the ordinary stethoscope.

In view of the foregoing report the Council on Physical Therapy voted to include the Western Electric 3-A Stethoscope in its list of accepted devices.

Western Electric 3-A Stethoscope

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

SULFANILAMIDE-LILLY (See THE JOURNAL, Oct. 23, 1937, p. 1365, and Revised Supplement to New and Nonofficial Remedies, 1937, p. 29)

The following dosage form has been accepted:

Sulfanilamide Tablets 7½ grains

SILVER NITRATE (See New and Nonofficial Remedies, 1937, p. 431)

Ampoules Silver Nitrate Solution 1 per cent Abbott. Each wax ampule contains approximately 0.5 cc of a solution of silver nitrate U. S. P. 1 per cent in chemically pure water. For the prevention of ophthalmia neonatorum two drops of the solution are instilled under the lower lid of each eye of the newborn after suitable cleansing.

Prepared by the Abbott Laboratories, North Chicago, Ill. No U. S. patent or trademark.

PROCAINE-ABBOTT (See New and Nonofficial Remedies, 1937, p. 69)

The following dosage form has been accepted:

Procaine Hydrochloride ½ grain Epinephrine ⅓ 000 grain Hypodermic Tablets. Each contains procaine hydrochloride Abbott 0.02 Gm. (⅓ grain) epinephrine 0.000016 Gm. (⅓ 000 grain) sodium bisulfite 0.0016 Gm. (140 grain) and sodium chloride sufficient so that when the tablet is dissolved in 1 cc of water the resulting solution is approximately isotonic.

SATURDAY, APRIL 2, 1938

WHEELER-LEA BILL GIVING FEDERAL TRADE COMMISSION JURISDICTION OVER FOODS, DRUGS, DEVICES AND COSMETICS BECOMES A LAW

Unfair and deceptive acts and practices in the exploitation and sale of foods, drugs, diagnostic and therapeutic devices and cosmetics in interstate and foreign commerce, even though not involved in commercial competition, will shortly come under the jurisdiction of the Federal Trade Commission through the operation of the Wheeler-Lea Act,¹ approved March 21 by the President. The act becomes effective on the expiration of sixty days immediately following the date of its approval. The jurisdiction of the Federal Trade Commission over unfair and deceptive acts and practices is now limited to such as constitute or form a part of unfair methods of commercial competition. The act just approved will give the commission, too, specific jurisdiction over the advertising of foods, drugs, diagnostic and therapeutic devices and cosmetics, whenever such advertising is disseminated in interstate and foreign commerce. Advertising that is disseminated or displayed only locally will come within the jurisdiction of the commission if it is designed to promote interstate and foreign commerce in the goods advertised. Only in event of proved danger to health or deliberate fraud will the offender be liable to fine and imprisonment. Under all other conditions, he will be subject only to a money penalty, to be recovered by civil suit, and then only after he has ignored a cease and desist order issued by the commission. A cease and desist order can be issued only after notice and hearing, with the right of appeal to the courts, a process that will normally occupy not less than ninety days. Appeals to the courts may possibly delay its effectiveness over a period of years.

After the new act becomes effective, no person, except as specifically stated, can lawfully disseminate any false advertisement of any food, drug, diagnostic or therapeutic device or cosmetic by mail. No one can dis-

seminate such an advertisement in interstate or foreign commerce by any means to induce the purchase of the merchandise named. Neither can any one disseminate a false advertisement even locally if it is designed to induce the purchase of such merchandise in interstate or foreign commerce. A "false advertisement" within the meaning of the act is any advertisement, other than labeling, that is misleading in a material respect. In determining whether an advertisement is or is not misleading, the commission must take into account not only representations made or suggested in it but also the extent to which it fails to reveal facts material in the light of such representations, or facts that are material with respect to the consequences which may result from the use of the commodity to which the advertisement relates, under the conditions prescribed in the advertisement or under such conditions as are customary or usual. In the case of a drug, however, no advertisement is to be deemed false that is disseminated only to the members of the medical profession, contains no false representation of a material fact, and includes or is accompanied in each instance by a truthful disclosure of the formula, showing quantitatively each ingredient. Publishers, radio broadcast licensees, and agencies or mediums for the dissemination of advertising, except the manufacturer, packer, distributor or seller of the commodity to which the false advertisement relates, are to be immune from punishment if they disclose, on request of the Federal Trade Commission, the name and post office address of the manufacturer, packer, distributor, seller or advertising agency in the United States that caused the dissemination of the false advertisement.

False advertising is to be regarded ordinarily as an unfair or deceptive act or practice and proceeded against by notice, hearing and the issue of a cease and desist order, subject to appeal to the courts. If, however, the commodity advertised may be injurious to health because of results from use under the conditions prescribed in the advertisement or under such conditions as are customary or usual, or if the advertisement is disseminated with intent to defraud or mislead, the advertiser may be prosecuted criminally without previous notice and fined and imprisoned. If the Federal Trade Commission believes that any person, partnership or corporation is disseminating or about to disseminate any false advertisement of a food, drug, diagnostic or therapeutic device or cosmetic and that the interest of the public requires that the dissemination of that advertisement be prevented or suspended pending final action by the commission, the commission may appeal to the court for an injunction or restraining order, which may be issued if it does not delay the delivery of any particular issue of a newspaper, magazine, periodical or publication, published at regular intervals, provided the publisher has not, in order to evade the requirements of the act, purposely concealed the misleading character of the advertisement so long

¹ Public Law No. 447—75th Congress. An Act to amend the act creating the Federal Trade Commission to define its powers and duties and for other purposes.

that any change necessary to make it truthful would delay publication of the periodical

The provisions of the new act that relate to advertising originated in bills designed to safeguard the public against fraud and danger to health through the distribution in interstate and foreign commerce of adulterated and misbranded foods, drugs, diagnostic and therapeutic devices and cosmetics. The advertising provisions in the present act were lifted bodily from the Copeland food and drugs act, S. 5, which has passed the Senate, and, after modification, were included in the act which has just been approved. Jurisdiction over the advertising of foods, drugs, diagnostic and therapeutic devices and cosmetics is therefore to be vested in the Federal Trade Commission, while jurisdiction over the labeling of such products will be left to the Secretary of Agriculture. There will be similar division of authority with respect to the general control of such merchandise. While the Secretary of Agriculture is still to retain specific control over adulteration and misbranding, the Federal Trade Commission can at any moment take jurisdiction on the ground that adulteration and misbranding constitute unfair or deceptive acts or practices and therefore come within its jurisdiction. Inevitably such division of authority with respect to labeling and advertising and such duplication of authority with respect to adulteration and misbranding will lead to conflicts. The enlarged jurisdiction of the Federal Trade Commission will necessitate an increase in personnel and laboratory resources, if effective work is to be done. The public should be aware of the situation and the medical profession must continue to investigate and to protect the public until it is satisfied that this act as administered is affording the protection that is required.

A NEW SOURCE OF BLOOD FOR TRANSFUSION

The theory that fetal blood possesses a high immunobiologic antitlastic quality against neoplasms caused Bruskin and Farberova¹ of the Oncologic Institute of Moscow to attempt the use of placental blood for massive transfusions during surgical treatment of malignant neoplasms. The blood was obtained from the umbilical vein and the placenta of the new-born. The amount obtainable from one placenta varied between 50 and 120 cc. It was found that the hemoglobin of the placental blood varied from 90 to 120 per cent (the method of determination not stated), erythrocytes from 5,000,000 to 6,000,000, and leukocytes from 8,000 to 16,000, with a definite lymphocytosis (from 32 to 46 per cent). The reticulocytes varied from 11 to 30 in 1,000 cells. The observers believe that placental blood contains a number of hormones of ovarian and anterior pituitary origin. The blood was conserved for

from six to ten days. Bruskin and Farberova estimate that two thirds of the 60,000 annual births in Moscow could be used for the provision of placental blood. An average of 50 cc from each birth would yield 2,000 liters, or an amount sufficient for from 6,000 to 8,000 blood transfusions.

Stavskaya² reported in 1937 on the use of retroplacental blood in the obstetric-gynecologic clinic of the Mother and Child Institute in Kiev. She likewise emphasized the distinguishing characteristics of the placental blood to be its high hemoglobin content, increased morphologic elements, considerable content of bilirubin, high sugar content, and low cholesterol and alkali reserve. The blood contains estrogen, gonadotropic substance and an epinephrine-like substance. It is also distinguished by its rapid coagulability. The amount of blood obtainable from a retroplacental hematoma varied from 80 to 300 cc. The isoagglutination properties of the placental blood are sharply defined and the blood grouping corresponds always to that of the mother's blood. Stavskaya found that the placental blood in vitro has little tendency to coagulate and may be kept without preservatives for from ten to twelve days.

Goodall, Anderson, Altmas and MacPhail³ have demonstrated that emptying the placenta of its blood does not appreciably influence either the time of its separation or its completeness. They have adopted much the same technic as did the Russian workers and confirmed all of the advantages claimed for the method. They have adopted, after some experimentation, a preservative proposed by the Moscow Institute of Hematology and consisting of sodium chloride 7 Gm, sodium citrate 5 Gm, potassium chloride 0.2 Gm, magnesium sulfate 0.004 Gm, and bidistilled water 1,000 cc. They found that it was not necessary to take cultures of the preserved blood because contamination does not take place at the low temperature at which the blood is preserved. Slightly progressive hemolysis was found to occur after the first fifteen days. Thus, however, they found to be no barrier to a normal transfusion. The reason for the innocuousness of this hemolysis lies in the fact that the hemolysis is small in quantity and is apparently inoperative in the recipient. They comment on the fact that the polycythemia of a child at birth leads to the destruction of a number of red cells when the lungs come into operation. The breaking down of these cells is the cause of many of the cases of hemolytic jaundice in the new-born. They advance this explanation to meet the argument that taking of blood from the placenta deprives the new-born infant of its rightful due. They found also that fetal blood contains from 20 to 35 per cent

³ Goodall, J. R., Anderson, T. O., Altmas, G. T. and MacPhail, F. L. An Inexhaustible Source of Blood for Transfusion and Its Preservation. *Surg. Gynec. & Obst.* 66 176 (Feb.) 1938 abstr. this is ue p 1148.

¹ Bruskin, Ya. M. and Farberova, R. S. Use of Umbilical and Placental Blood for Massive Transfusions in Surgery. *Soviet vresh. zhur* 10 1546 (Oct. 30) 1936 abstr. J. A. M. A 107 2098 (Dec. 19) 1936.

more coagulation power than that of adult blood. This appears to be nature's provision to prevent exsanguination of the new-born in animals in which the cord is torn or bitten. This property presents an advantage in transfusion for hemorrhage. The authors feel that preserved blood has many advantages over fresh blood. It eliminates food and other extraneous allergic reactions. In many transfusions there did not occur a single untoward reaction or rise of temperature. Two or more fetal bloods may be given simultaneously if necessary after separate matching. They suggest that a maternity section of a general hospital is capable of giving more than enough blood for the needs of the whole institution and that the blood can be sent to other institutions in adequate vacuum containers if the group of the recipient is known. The method appears to be an efficient and inexhaustible source of blood for transfusion.

SYNERGIC EFFECTS OF ANTIGENS

When two or more simple antigens are injected simultaneously into laboratory animals, the usual antibody response may be modified. This modification may be a suppression, perversion or augmentation of specific antibody formation against one or more of the individual antigens. The earliest description of this phenomenon was the observation by Burky and his co-workers¹ at Johns Hopkins University that rabbit lens proteins are not antigenic for rabbits but that the lens protein complex can be rendered antigenic by simple fractionation. The alpha fraction causes high titer precipitin production in rabbits. While both the beta and gamma fractions are antigenically inactive, each has the property of suppressing antibody production against alpha proteins.

A teleological explanation of this relationship might assume that the crystalline lens had developed a protective mechanism consisting of specific inhibins and that the absorption or internal secretion of these inhibins prevent the formation of antigens precipitin which otherwise might cause degenerative changes in the eye. If this explanation is correct, a biologic theorist would postulate the existence of similar local antigenic inhibins in other highly specialized organs or tissues, particularly the endocrine glands. Endocrine therapy is often self limiting because of the antigenicity of available preparations of hormones. The resulting antiendocrine immunity not only limits therapeutic action but may lead to autotoxic degeneration of homologous endocrine glands.

Of even greater clinical promise is the opposite phenomenon, the augmentation of antibody response in certain mixed antigens. Burky² for example found that, while pollen extracts are practically nonantigenic for rabbits, high-titer antibodies can be produced against pollens if they are "synergized" or "potentiated" by the addition of staphylococcus toxin. Swift and

Schultz³ of the Rockefeller Institute have confirmed this observation and have found that it is not necessary to mix the staphylococcus toxin with the nonantigenic protein before injection. The two may be injected independently, as by different routes or at different times, and still produce augmented antibody response. They also found several substances other than staphylococcus toxin that can function as antigenic energizers.

Among the latest confirmations of the Burky phenomenon are the observations by Magerl⁴ of the Hygienic Institute at the University of Innsbruck, who studied the synergic antigenicity of different blood mixtures. Magerl found that horse, ox, swine and sheep erythrocytes would each cause prompt production of specific amboceptor in rabbits but a mixture of two or more specimens of blood is often relatively nonantigenic. Other mixtures, such as of sheep and horse erythrocytes, cause about ten times the normal antibody response. The amboceptors appear more promptly, are of higher titer and persist longer than in the control injections with individual sheep or horse blood.

Apparently an attempt has not yet been made to formulate a theory as to the chemical or physiologic mechanism by which these antigenic mixtures inhibit or augment antibody synthesis. The discovery of these two synergic phenomena, however, stimulates hope of renewed clinical victories in many fields of vaccine therapy and serum therapy. A nonantigenic solution of posterior pituitary or a successfully "potentiated" tuberculin are not beyond the realm of possibility.

Current Comment

COMMERCIAL ASPECTS OF J THOMPSON STEVENS—A "MIRACLE MAN"

In the *Cosmopolitan* for March 1938 Mr. Rex Beach, pursuing his devious course through his conception of the great prophets in medicine, devotes some space to the work of Dr. J. Thompson Stevens of New York City and lists him with the "Modern Miracle Men." Among the previous inhabitants of niches in Mr. Rex Beach's hall of medical fame are Mahlon Locke of Canada, Hiss of California and a number of nondescript faith healers and promoters of unestablished methods of more or less scientific disrepute. The selection of Dr. Stevens would seem to be extraordinary, since he is listed as a member of the Radiological Society of North America and of the American Roentgen Ray Society as well as of the New York State Medical Society and the New Jersey State Medical Society. A brief analysis of the article by Mr. Beach indicates that Dr. Stevens is, in Mr. Beach's opinion, capable of performing miracles in the healing of infections of the sinuses and in the removal of the tonsils by the use of the roentgen ray. The scientific evidence available as to these perform-

¹ Burky, E. L. and Woods, A. C. *Arch. Ophthalmol.* 57: 41 (Jan.) 1928.
Woods, A. C., Burky, E. L. and Woodhall, M. B. *Tr. Am. Ophthalm. Soc.* 29: 168, 1931.

² Burky, E. L. *J. Allergy* 5: 466 (July) 1934.

³ Swift, H. F. and Schultz, M. P. *J. Exper. Med.* 63: 703 (May) 1936.

⁴ Magerl, J. *Ztschr. f. Immunitätsforsch. u. exper. Therap.* 90: 327 (May 27) 1937.

ances is obviously not such as to support these contentions. What appears to be an unusual feature of this exploitation of Dr Stevens is the development of a commercial setup for suitable exhaustion of the available profits from this type of promotion. In some manner a young woman called Miss Phoebe Elkins seems to be associated with the promotion. Characterizing herself as a publicity woman, she has called on physicians indicating that it is her business to arrange publicity for doctors and that she aided Mr Beach in finding Mahlon Locke and Stevens for his literary purposes. Writing on the stationery of Dr Stevens, she indicates also that she arranges medical consultations for people who are attracted by the articles in the magazine either with the "hero" of the article by Mr Beach or with associates in neighboring cities.

"We are greatly in need of a good diagnostician and Roentgenologist to become affiliated with us in your vicinity. As you undoubtedly know Dr Stevens is considered one of the finest Roentgenologists in the East and because of his ability we are deluged with requests for an associate in various parts of the country. From what I understand you fill the above qualifications. Therefore, I am wondering if you would enjoy an affiliation in your vicinity with our main offices, namely, New York City and Montclair, New Jersey."

These, it appears, will be asked to treat the patients and then remit to her one third of the gross amount to be received from such treatments. The physician who supplies the information concerning his contact with Miss Elkins was offered the concession in a neighboring city and was informed that there was some \$25,000 worth of business which had been developed by the publication of Mr Beach's article. As we go to press information is received indicating that the astute promoters are also recommending application of the x-rays for the control of goiter. Obviously this entire performance smells to high heaven from an ethical point of view. The public needs protection against such unwarranted commercial exploitation. Incidents of this type are the actual proof of the necessity for principles of ethics to control advertising and exploitation of physicians.

THIAMIN CHLORIDE AND NICOTINIC ACID IN PELLAGRA

Elsewhere in this issue (page 1081) is an article by Spies and Ating on the effect of the administration of vitamin B₁ on the peripheral neuritis of pellagra. Observations are recorded in six cases of classic pellagra with peripheral neuritis, in four of which pellagra had developed after alcohol had been largely substituted for a balanced dietary. Irrespective of the cause of the pellagra, prompt relief of spontaneous neuritic pain resulted from the intravenous injection of thiamin chloride (crystalline vitamin B₁ hydrochloride). These observations suggest that vitamin B₁ deficiency plays a part in the development of clinical manifestations of peripheral neuritis associated with pellagra. Since some patients fail to absorb vitamin B₁ by mouth, it seems to be necessary to give them parenteral injections. The vitamin B₁ does not appear to cure the glossitis and stomatitis of pellagra but nicotinic acid, which has been referred to in an editorial

in THE JOURNAL¹ as well as in a recent article by Spies and his co-workers,² does relieve these symptoms. Taken together these interesting observations made by the Cincinnati investigators leave little doubt that pellagra, or at least some of its manifestations, is the result of more than one factor. They have demonstrated that all types are benefited within twenty-four to forty-eight hours after the administration of nicotinic acid. Certainly both thiamin chloride and nicotinic acid deserve further intensive study in their relation to pellagra.

GOVERNOR CHANDLER OF KENTUCKY GIVES HIGH PRAISE TO AMERICAN PHYSICIANS

Refreshing as a spring breeze is the following statement by Gov A B Chandler of Kentucky at the dedication of a new wing of the State Tuberculosis Sanitarium at Hazelwood, Ky, March 28.

Kentuckians are very proud of the distinguished history of its medical profession. The first medical school in the West was Transylvania at Lexington, and no institution in this country made a greater contribution to the public health and welfare of its day.

Now, for more than a hundred years, those in charge of public affairs have left medical and health problems to the doctors. More progress has been made in public health and medical service than in any other human activity in Kentucky. I am convinced that this is because the responsibility for it has been placed squarely on the shoulders of the medical profession.

In the last fifty years, the death rate has been reduced two thirds, acute diseases have been reduced as much as in any other state, we have more full-time health departments than any other state. This organization has been entirely medical from its beginning, and its principles have been determined and its activities controlled by physicians of the state. We realize fully that our doctors have made the largest contribution in value to the welfare of our citizens of any group. So far as it has been possible for them to do so, they have given the same service to rich and poor alike. Seventy-five years ago the average age at death in Kentucky was 32 years, last year it was 61 years. This of course, means that many more people are living in the older groups.

We must realize that this older average population presents us with a tremendous problem, we must make the same study and take the same care of chronic and degenerative diseases that formerly we have so successfully accomplished with the infectious diseases.

Opportunists talk very glibly about health insurance, the socialization of medicine and the regimentation of physicians as the remedy for this situation. Such suggestions will receive no support by the people of Kentucky. We will continue to be guided in regard to public health and medical service by our doctors.

Recently Dr Irvin Abell, President-Elect of the American Medical Association, has informed me of the study of medical service and the provision for medical care for the indigent, which study is being undertaken by the American Medical Association. He properly advances the concept that the organized medical profession is the family physician of the commonwealth and that it should examine the resources for medical service and that it should show exactly what they should do to obtain all the benefits of modern scientific medicine.

Realizing that the profession has been very busy in reducing the death rate from acute and infectious diseases, we will patiently await their examination and diagnosis in regard to

¹ Pellagra and Nicotinic Acid editorial J A M A 110 289 (Jan 22) 1938

² Spies T D Cooper Clark and Blankenhorn M A The Use of Nicotinic Acid in the Treatment of Pellagra J A M A 110 622 (Feb 26) 1938

the medical conditions which confront us, and we will be guided by them with perfect confidence that they will continue to give our people all that modern science can give toward making Kentucky the healthiest, the happiest and the most effective people in these United States

The medical profession is proud of this tribute to its record of the past, grateful for this judgment of what medicine is trying to do in the present, and appreciative of the confidence of Governor Chandler in medicine's future

ALABAMA

State Medical Meeting at Mobile April 19-21—The Medical Association of the State of Alabama will hold its annual meeting at the Battle House in Mobile, April 19-21, under the presidency of Dr Edward S Sledge, Mobile. The following speakers will participate

- Dr Lawrence H Hinton, Mobile Review of Some External Eye Diseases
- Dr James Otis Lisenby, Atmore, Diagnosis and Treatment of Tumors of the Breast
- Dr Frank A Kay, Tuscaloosa, Metrazol Treatment of the Psychoses
- Dr Chalmers H Moore, Birmingham, Head Injuries
- Dr Joe H Little, Mobile, Progress in the Treatment of Diabetes
- Dr Benjamin F Byrd, Nashville, Tenn., The Insurance Triangle Applicant Examiner Company
- Dr Robert S Hill, Montgomery, Medicine as a Profession
- Dr John H Musser, New Orleans, Treatment of Organic and Inorganic Diseases of the Stomach
- Drs John W Means and Camille J DeLor, Columbus, Surgery of Biliary Passages with Reference to the Hazards and Their Management
- Dr Charles N Leach, Montgomery, Rabies
- Dr Albert Graeme Mitchell, Cincinnati, Practical Application of Studies on Gastro Enteritis
- Dr Henry F Helmholtz, Rochester, Minn, Abdominal Tumors in Childhood
- Dr Oscar W Betha, New Orleans, The Pneumonias

A symposium on obstetrics will be presented Tuesday evening by Drs James R Garber, Birmingham, and Archie E Thomas, Montgomery. Dr Thomas M McMillan, Philadelphia, will deliver the Jerome Cochran Lecture Wednesday morning on "An Optimistic View of Some Problems of Heart Disease." Dr Charles A Mohr, Mobile, will open a public meeting Wednesday, the speakers will be Dr Alice C Evans, Washington, D C, on "Undulant Fever as a Public Health Problem" and Dr James N Baker, state health officer, Montgomery, "What the State Department of Public Health Is Doing for the Citizens of Alabama." The thirteenth annual meeting of the Woman's Auxiliary to the state medical association will be held at the Cawthon Hotel in Mobile April 19-21. The thirteenth annual session of the Alabama Pediatric Society will be held at the Battle House April 18. The speakers will include Dr Mitchell on "Is the Pediatrician a Psychiatrist?", Dr Helmholtz, "Treatment of Acute Urinary Infections in Childhood", Dr Joseph Yampolsky, Atlanta, Ga, "A Comparative Review of the Drugs Used in the Treatment of Syphilis." Drs Mitchell and Yampolsky will also address the evening session.

CALIFORNIA

Course on Diseases of Digestive Tract—The University of California Medical School, San Francisco, will conduct a short graduate course in diseases of the digestive tract April 13-16. Instruction will be given by lectures, demonstrations and surgical clinics. The fee will be \$20. Further information may be obtained from Dr Langley Porter, dean of the medical school, Medical Center, San Francisco.

Society News—A symposium on rabies was presented before the Pasteur Society of Central California March 3 in San Francisco by Drs Jacob C Geiger, director of health of San Francisco, Harry E Foster, medical director, Cutter Laboratories Berkeley and Jacob Traum, M.S., professor of veterinary science, University of California.—Dr Emile F Holman discussed "Medicine in Scandinavia" before the San Francisco County Medical Society March 8 and Karl F Meyer, Ph.D., "Medical Impressions from a Recent European Trip" both talks were illustrated with colored slides.—Dr Clifford

B Walker was recently elected president of the Los Angeles Society of Ophthalmology and Otolaryngology and Dr John P Lordan, secretary.—At a joint meeting of the Los Angeles County Medical Association with the Southern California Retail Druggists Association, March 17, Mr Frank E Mortensen, secretary of the latter group, among others, discussed "Prospective Legislation of Interest to Medicine and Pharmacy."—A round table discussion on "Treatment of Infection by Means of Small Doses of Insulin" was a feature of a joint dinner meeting of the Los Angeles Society of Ophthalmology and Otolaryngology and the Research Study Club of Los Angeles, March 28.

COLORADO

First Full Time Health Unit—The first full time county health unit in Colorado was opened in Otero County February 7. Dr Lynn J Lull, formerly in private practice in Olathe, has been appointed health officer with headquarters at La Junta. The unit is maintained jointly by the county and the state in cooperation with the Otero County Medical Society. Plans are under way for the organization of a second unit.

CONNECTICUT

The Ferris Lecture in Anatomy—Samuel R Detweiler, Ph.D., professor of anatomy, Columbia University College of Physicians and Surgeons, New York, delivered the fifth Harry Burr Ferris Lecture at the Yale University School of Medicine, New Haven, March 2, his subject was "Vertebrate Visual Receptors."

Society News—Dr Jerome M Lynch, New York, will address the New England Proctologic Society in New Haven April 22 on "Lynch's Modification of the Perineal Operation." The society was organized in Hartford in November 1937 with Dr Albert R Keith, Hartford, president, Dr Frederick S Ellison, Hartford, secretary, and Dr Simon B Kleiner, New Haven, chairman of the executive committee.—Dr Harry M Zimmerman, New Haven, will address the Fairfield County Medical Association April 12 in Bridgeport on "Vascular Diseases of the Central Nervous System." Dr Clarence L Robbins, New Haven, will discuss "Edema, Its Differentiation and Treatment."

GEORGIA

Society News—Dr William G Hamm, Atlanta, among others, discussed "Fractures of the Jaw" before the Fulton County Medical Society March 17. Dr Edgar F Fincher Jr, Atlanta, among others, presented a paper before the society, February 3, on "Sciatica and Low Back Pain—The Result of Ruptured Intervertebral Cartilage."

Dr Warren Lectures in Atlanta—Dr Shields Warren, Boston, delivered a series of lectures at the Academy of Medicine, Atlanta, under the auspices of the Atlanta Clinical Society March 23-25. His subjects were "Recent Advances in the Pathology of Diabetes Mellitus," "Pathology of the Thyroid Gland" and "Radiosensitivity of Tumors."

ILLINOIS

Personal—Dr Robert H Bell, health officer of Carlville, has been appointed full-time superintendent of the district health unit composed of the counties of Scott, Morgan, Greene, Calhoun, Jersey and Macoupin.

Society News—A joint meeting of the Mercer and Rock Island county medical societies in East Moline, March 8, was addressed by Drs John S Coulter, Chicago, on "Hyperpyrexia" and "Home Treatment of Chronic Arthritis with Physical Agents."—Dr Paul H Harmon, Chicago, addressed the Adams County Medical Society, Quincy, February 14, on "The Illinois Plan for the Care of Crippled Children."

Chicago

Dr Joslin Will Address Medical Society—Dr Elliott P Joslin, clinical professor of medicine, Harvard University Medical School, Boston, will address the Chicago Medical Society April 6 on "Present Conceptions of Diabetes Mellitus."

Dr Pearl to Speak on Longevity—Raymond Pearl, Ph.D., professor of biology, Johns Hopkins University School of Medicine and the School of Hygiene and Public Health, Baltimore, will deliver a public lecture at Thorne Hall April 15, under the auspices of the Institute of Medicine of Chicago. The title of his lecture will be "Long Life and Living."

Society News—Drs Morris Fishbein, Editor, THE JOURNAL and Roscoe G Leland, Director, Bureau of Medical Economics American Medical Association will address the

North Side Branch of the Chicago Medical Society at the Drake Hotel April 7, 8 p m., their subjects will be "Medicine and the National Policy" and "Hospital Service Plans" respectively

Hospital Groups Merge—The Chicago Hospital Association and the Chicago Hospital Council have been consolidated, the former to be the administrative section, according to the Chicago Tribune. Membership in the association was restricted largely to administrative heads of hospitals, while the council included superintendents, board presidents and chiefs of staff. The council had twenty-six member hospitals and the association twenty-three.

Measles Unusually Prevalent—There were 24,363 cases of measles reported during the first seventy-six days of 1938, according to the Chicago Tribune March 21, recording a new high total for the city. This total was 164 more cases than that recorded for the entire year of 1935, the previous peak year. In the same period in 1937 only 259 cases were reported, while the total for the year was only 496, it was stated. The largest number of cases reported in a single day was 743 on March 10. Since the first of the year there have been twenty-one deaths attributed to measles, while in the same period in 1935 there were nineteen.

INDIANA

New Department Organized—The creation of a new department of bacteriology and public health and a new department of pathology at Indiana University School of Medicine, Indianapolis is announced. The former department of bacteriology and pathology was divided and bacteriology was combined with the division of public health. Dr Thurman B. Rice, professor of bacteriology and public health, has been made chairman of the new department and Dr Frank Forry, professor of pathology, chairman of the new department of pathology. The pathology department has two divisions, one of general pathology with Dr Forry as chairman and a division of clinical pathology with Dr Clyde G. Culbertson as chairman, according to the *Bloomington Student*.

KENTUCKY

Personal—Dr Frank M. Rogers, formerly of Coleman, Ga., has been appointed health officer of Crittenden County with headquarters at Marion—Dr Michael M. Hall, Campbellsville, was appointed coroner of Taylor County to succeed the late Dr Benjamin T. Black—Dr Elmer K. Umberger, formerly of Trinity, Texas, has been appointed health officer of McCreary County.

Dr Abell to Receive Notre Dame Medal—The Laetare Medal, awarded annually by the University of Notre Dame, is to be awarded to Dr Irvin Abell, Louisville, President-Elect of the American Medical Association. In the announcement Father John O'Hara, president of the university, said:

The merit of Dr Abell in his profession has been signally recognized in his election to the presidency of the American Medical Association and his varied service to city, state and nation as surgeon, citizen, soldier and Christian gentleman has endeared him in the esteem of a numerous and extensive public benefited by his years of devotion to the complete welfare of his fellow men.

The Laetare Medal was originated by Notre Dame in 1883 and Dr Abell is the fifty-sixth recipient.

Society News—Dr Emmet F. Horine addressed the Louisville Medical Surgical Society, March 11, on "Mercurial Diuretics"—A symposium on diseases of the gallbladder was presented before the Boyle County Medical Society, Danville, February 15 by Drs John Rice Cowan, George M. McClure, Stuart P. Hemphill, Oscar L. May and S. B. Sharp, D.D.S., all of Danville—At a quarterly meeting of the Southwestern Kentucky Medical Association in Benton February 8, Drs George F. Cummins, Metropolis, Ill., and Earnest R. Goodloe, Paducah, spoke on "Clinical Findings in Thyroid Deficiency" and Epistomy—How, When and Why" respectively—Dr Arthur B. Barrett, Lexington, addressed the Bourbon County Medical Society, Paris, January 27 on "Endocrinology in Obstetrics and Gynecology" and George R. Smith, Lexington attorney, on "Medical Aspects of the Workmen's Compensation Act."

MAINE

Society News—Dr Maxwell Finland, Boston, discussed "The Treatment of Pneumonia" before the Cumberland County Medical Society February 25—At a recent meeting of the Portland Medical Club Dr Francis W. Hanlon spoke on "The Relation Between Acute Visceral Infections and the Alarm Reaction." Dr Thomas Tetreau addressed the club recently

on "Milk as a Factor Influencing the Infant Mortality Rate in Portland"—The Kennebec County Medical Association was addressed in Waterville February 17 on "Recent Developments in the Diagnosis and Treatment of Diseases of the Stomach"—At a meeting of the Penobscot County Medical Association in Bangor recently Dr Champ Lyons, Boston, spoke on "Modern Methods in the Treatment of Pyogenic Infections."

MARYLAND

Society News—At a meeting of the Baltimore City Medical Society, March 4, a paper by Drs John E. Howard and Samuel A. Vest Jr was presented by Dr Vest, the subject was "Clinical Experiments in the Use of Testosterone." Dr Herbert Schoenrich discussed "Sulfanilamide in Clinical Gonorrhea"—Dr Thomas Nelson Carey, Baltimore, addressed the Carroll County Medical Society in Westminster January 26 on "Use of Serum in Treatment of Pneumonia"—Dr Joseph H. Barach, Pittsburgh, addressed the Allegany-Garrett County Medical Society at Cumberland, February 25, on "Science of Nutrition and the Treatment of Diabetes."

The De Lamar Lectures—The remaining lectures in the De Lamar series at the Johns Hopkins University School of Hygiene and Public Health, Baltimore, will be delivered by

Dr Thomas Francis Jr, International Health Division of the Rockefeller Foundation, New York, April 12, "The Immunology of Epidemic Influenza."

Edmund V. Cowdry, Ph.D., professor of cytology, Washington University School of Medicine, St. Louis, April 19, "Cellular Changes in Leprosy."

Dr Franz Weidenreich, honorable director, Cenozoic Research Laboratory, National Geological Survey of China, Sinanthropus Pekinensis and Its Significance for the Problem of Human Evolution. The date of this lecture had not been decided.

Robert Matheson, Ph.D., professor of economic entomology, Cornell University Agricultural Experiment Station, gave a lecture in this series March 8 on "Biology of Anophelines with Special Reference to Those of North America."

MICHIGAN

New Professor of Pathology—Dr Edgar H. Norris, Minneapolis, teaching assistant in pathology, University of Minnesota Medical School, Minneapolis, has been appointed professor and head of the department of pathology at Wayne University College of Medicine, Detroit, according to the *Minneapolis Journal*. The appointment is effective next fall. Dr Norris graduated at the University of Minnesota Medical School in 1919.

Physicians Honored—Dr Heman B. Kiehl, Lapeer, was given a dinner by the Lapeer County Medical Society February 10 to observe his completion of more than fifty years in the practice of medicine. He was presented with a chair. Dr Kiehl helped to organize the Ogemaw, Montmorency, Crawford, Oscoda, Roscommon and Otsego Medical Society, serving as vice president at the time of its establishment. He was formerly health officer of Rose City and is an alumnus of the College of Physicians and Surgeons, Keokuk, Iowa, class of 1887—Dr Robert B. Armstrong, Charlevoix, was recently chosen the first life member of the local Kiwanis Club, he was mayor of Charlevoix in 1907—The Jackson Academy of Medicine and Dentistry gave a dinner in honor of Dr Joseph C. Kugler in Jackson, January 27, to mark his retirement from active practice, Dr Horace W. Porter, Jackson, was toastmaster.

MINNESOTA

Janitor Performs Illegal Operation—Frank Kish, a janitor, pleaded guilty in Ramsey County March 1 to a charge of performing an abortion and was sentenced to a term of eighteen months at hard labor in a state penal institution. Kish admitted having performed about twenty-five abortions, charging from \$5 to \$30. He had only an eighth grade education and no medical training whatever, the state board of medical examiners reported.

Society News—The Minnesota Pathological Society was addressed in Minneapolis March 15 by Dr Abe B. Baker on "Subdural Hematoma" and Drs Arild E. Hansen and Irvine McQuarrie and Mildred R. Ziegler, Ph.D., on "Disturbances in the Osseous and Lipid Metabolism in a Child with Primary Carcinoma of the Liver"—The Minnesota Academy of Medicine was addressed in St. Paul March 9 by Drs Frederic E. B. Foley on "Operative Division of a Unilateral Fused Kidney" and Hendrie Grant, on "Malignant Hypertension"—Dr George R. Dunn has been elected president of the Minneapolis Surgical Society, succeeding Dr Otto W. Yoerg.

MISSOURI

Annual Spring Clinic—The St Joseph Clinical Society will hold its seventh annual spring clinic at the Hotel Robideaux, St Joseph, April 13-14. There will be no registration fee. The speakers will include

Dr. James O Donoghue, St Joseph, Advances in X Ray and Radium Therapy
Dr. Vincil Rogers Deakin, St Louis, Treatment of Acidosis in Renal Insufficiency
Dr. Robert D Alexander, St Louis, Cancer of the Colon and Rectum
Dr. Ernest Sachs, St Louis, Brain Tumor
Dr. Ralph V Byrne, St Joseph, New Clinical and Laboratory Concepts of Hyperthyroidism
Dr. Thomas L Howden, St Joseph, Hypertension of the Menopause
Dr. Robert S Minton, St Joseph, Eye Injuries
Dr. Thomas G Orr, Kansas City, Cancer of the Breast
Dr. Rollin Russell Best, Omaha, Advances in the Treatment of Biliary Tract Disease
Dr. Warren H Cole, Chicago, Intestinal Obstruction
Dr. Horace M Korns, Iowa City, Diagnosis and Treatment of Peripheral Vascular Disease
Dr. Henry H Turner, Oklahoma City, Okla, Diagnosis and Treatment of Endocrine Disorders

At the luncheon the first day Dr Sachs will show a "Travelogue to Guatemala." In the evening a joint dinner meeting will be held with the Buchanan County Medical Society with Drs. Hugo Ehrenfest, St Louis, and Clifford G Grulee, Evanston, Ill., as the speakers on "Birth Injuries" and "Intracranial Hemorrhage of the Newborn" respectively. At a dinner the following evening Dr Cole will speak on "Pancreatitis."

NEBRASKA

Society News—Dr. Sanford R Gifford, Chicago, was the guest speaker before the Omaha-Douglas County Medical Society, Omaha, February 8, on "Recent Advances in Ophthalmology." Dr. Joseph D McCarthy, Omaha, discussed "Questionable Cholecystitis—Cholecystectomy and Its Aftermath" and Dr. Charles McMartin reported a case of vulvar verruca acuminata. Drs. Edward H Hashinger and Ferdinand C Helwig, Kansas City, Mo., addressed the Lancaster County Medical Society, Lincoln, February 1, on "Various Phases of Obesity with Particular Emphasis on Endocrine Therapy" and "The Diagnostic and Therapeutic Importance of Endocrine Activity in Neoplastic Disease" respectively. Drs. Warren Thompson and Joseph D McCarthy, Omaha, addressed the Madison Six County Medical Society, Norfolk, January 18, on heart disease.

NEW YORK

Society News—Dr. William Hadden Irish, New York, addressed the Westchester County Medical Society, White Plains, March 15, on "Common Disabilities of the Knee Joint." Dr. William F Rienhoff, Baltimore, addressed the Medical Society of the County of Albany March 23 on "Diagnosis and Treatment of Carcinoma of the Lung and Allied Conditions Such as Bronchiectasis and Pulmonary Abscess."

Cruising X-Ray Laboratory for Silicosis Tests—The New York State Department of Labor has fitted a traveling x-ray laboratory to be sent to industrial centers where dust hazards are known or suspected to exist, the *New York State Journal of Medicine* reports. The traveling laboratory is 17 feet 9 inches long and 7 feet 4 inches wide. The rear half contains a reception and examining room, the other half the lead lined x-ray room.

Outbreak of Septic Sore Throat—An outbreak of septic sore throat involving 300 cases with two deaths up to February 26 was reported to the state department of health recently from Norwood, a village in St Lawrence County. Of 180 patients seen during an investigation 87 per cent had used raw milk from a single dairy. A milker on the dairy farm became ill with sore throat January 28 and later two cows were found to have acute mastitis. The milk was pasteurized and no new cases were reported up to March 7, *Health News* stated.

New York City

Gifts to New York University—The following are among the largest in a list of gifts to New York University for research in medicine:

Mrs. George B deLong \$10,000 for the department of pediatrics
The Commonwealth Fund \$8,750 for research in obstetrics and gynecology
Lucius V Littauer \$4,000 for studies on pneumonia
Phi Delta Epsilon fraternity \$2,200 to establish the John Wyckoff Lectureship Fund
Rockefeller Foundation \$500 for research in cellular physiology
Committee for the Study of Suicide Inc. \$3,250 for study of suicide by the department of psychiatry at Bellevue Hospital
Friedman Foundation Inc. \$1,800 for the Child Neurology Research Fund
International Cancer Research Foundation \$1,500 for research in cancer

Personal—Drs. Charles McDowell, emeritus professor of physiology, and Orlando S Ritch, a trustee of New York Medical College and Flower Hospital, were entertained at a luncheon March 9 in honor of the sixtieth anniversary of their graduation from the college. Dr. Francis Peyton Rous of the Rockefeller Institute for Medical Research has been elected a corresponding member of the Academy of Sciences, Paris, in the division of the biologic sciences.

Dr. Jelliffe Honored—Friends of Dr. Smith Ely Jelliffe have arranged a celebration of his thirty-fifth anniversary as editor of the *Journal of Nervous and Mental Disease*, to be held at the New York Academy of Medicine April 22. A symposium on neuropsychiatry will be presented at an afternoon meeting with the following program:

Dr. Earl D Bond, Philadelphia, Balance in Psychiatric Research
Dr. George Draper, New York, The Man Factor in Disease
Dr. Frederick Tilney, New York, New Interpretation of the Hippocampus
Dr. Oskar Diethelm, New York, Psychiatry and Neurology in the Last Fifty Years
Dr. Karl A Menninger, Topeka, Kan, Somatic Correlations with the Unconscious Repudiation of Femininity in Women

Dr. Adolf Meyer, Baltimore, will open the program and Dr. Jelliffe will preside. In the evening there will be a dinner at which the following speakers will pay tribute to Dr. Jelliffe: Drs. Abraham A Brill, Louis Casamajor, Henry Alsop Riley, all of New York, and Richard H Hutchings, Utica. Dr. Foster Kennedy will be toastmaster.

OHIO

Northern Tri-State Meeting—The annual meeting of the Northern Tri-State Medical Association will be held in Findlay April 12. Among the speakers will be:

Dr. Warren H Cole, Chicago, Hyperthyroidism
Dr. Max Thorek, Chicago, Electrosurgical Obliteration of the Gallbladder
Dr. Irving S Cutter, Chicago, Therapeutics of Later Years of Life
Dr. Gilbert J Thomas, Minneapolis, Infections Other Than Tuberculosis of the Urinary Tract
Dr. James S Speed, Memphis, Tenn, Central Fractures of the Neck of the Femur
Dr. Max Cutler, Chicago, Indications and Limitations of Radiation in the Treatment of Cancer
Dr. Alan Brown, Toronto, Some Common Disturbances in Children Frequently Handled Incorrectly

Medical Library Association—Dr. Carl H Lenhart was elected president of the Cleveland Medical Library Association at its annual meeting in January. Dr. Lenhart has been directing librarians of the association for eighteen years. Dr. Clyde L Cummer, chairman of the board of trustees, reported that the association now has assets amounting to about \$400,000 in addition to the Allen Memorial Library building adjoining Western Reserve University. It has 52,000 volumes and receives 434 medical journals. During the past year 10,000 visits to the library were recorded, only 3,000 were visits from members, the remainder being from students and the general public. A portrait of the late Dr. Alfred A Jenkins, president of the library association at his death Nov. 19, 1937, was presented on behalf of his family.

PENNSYLVANIA

Hospital News—Ground was broken March 8 for the new Montgomery Hospital, Norristown, the cost of which is estimated at \$525,000. The Greene County Memorial Hospital was recently opened in Waynesburg. It has a capacity of seventy beds and cost \$125,000 of which \$70,000 was a loan from the federal government. \$30,000 was appropriated by the county and \$25,000 was raised by public subscription.

Society News—Dr. Hobart A Reimann, Philadelphia, addressed the Lycoming County Medical Society, Williamsport, March 11, on "Recent Advances in the Treatment of Certain Infectious Diseases." Dr. George J Kistlin, Pittsburgh, addressed the McKean County Medical Society, Bradford, January 18, on pneumonia control. An obstetric and pediatric institute was presented at a meeting of the Westmoreland County Medical Society at the Mountain View Hotel near Greensburg, March 22, under the auspices of the state medical society. The speakers, all of Pittsburgh, were Drs. David Benjamin Martinez, William Paul Dodds, Charles J Barone, William W Briant Jr., Henry T Price and David H Boyd.

Philadelphia

Medical College News—The Woman's Medical College of Pennsylvania celebrated its eighty-eighth anniversary, March 11. Dr. Martha L Bailey, Dillsburg, presided and the speakers were Drs. Lida Stewart Cogill, Philadelphia, Kate Campbell Hurd Mead, Haddam, Conn., and Henry D Jump.

Society News—Speakers at a meeting of the Physiological Society of Philadelphia, February 21, included Drs. Dile R. Coman, on "The Effect of Sulfanilamide on Chemotropism of Leukocytes," and Paul E. Adolph and John S. Lockwood, "The Use of Sulfanilamide in Experimental Hemolytic Streptococcal Meningitis"—Dr. Ward J. MacNeal, New York, addressed the Eastern Pennsylvania Chapter of the Society of American Bacteriologists, February 22, on "Bacteriological Service in Septic Conditions"—A program of ten minute papers on cancer was presented at a meeting of the Philadelphia County Medical Society, March 9, by the following physicians: Drs. Ralph S. Bromer, Bryn Mawr, Willard S. Hastings, Sigmund S. Greenbaum, George M. Dorrance, Howard H. Bradshaw, William Bates, William H. MacKinney, Dorothy C. Blechschmidt and William Wayne Babcock—Dr. Maurice E. Binet Vichy, France, addressed a special meeting of the society, February 25, on "Hepatic Insufficiency."

Pittsburgh

Pediatric Survey—The Allegheny County Medical Society is sponsoring a pediatric survey for graduate physicians with no limit on the number permitted to register, the first of its type offered by the society in its twelve years of presenting graduate courses. Sessions were held at the Children's Hospital and Magee Hospital March 14 and 21, Allegheny General Hospital March 28, succeeding ones will be at the Pittsburgh Home for Babies, Watson Home for Crippled Children, Tuberculosis League, Municipal Hospital for Contagious Diseases and the Children's Hospital. Dr. Theodore O. Elterich is general chairman for the course.

Society News—Dr. Max M. Peet, Ann Arbor, Mich., delivered the Stewart Memorial Lecture of the Pittsburgh Academy of Medicine, March 22, on "Treatment of Hypertension by the Subdiaphragmatic Resection of the Splanchnic Nerves"—Guest speakers at a meeting of the Allegheny County Medical Society, March 15, were Dr. Benjamin I. Golden, Elkins, W. Va., on "Present Day Status of the Inguinal Hernia, with Discussion of Its Recurrence" and Rabbi Solomon B. Freehof, Pittsburgh, on "The Citadel of American Medicine"—At a meeting of the Pittsburgh Surgical Society March 29 the speakers were Drs. Daniel P. Greenlee, on "Adenoma of Islets of Langerhans with Hyperinsulinism," Otto C. Gaub, "Errors in Development of the Intestinal Tube Below the Stomach from the Surgical Standpoint" and Lyndon H. Landon, "The Surgical Problem of Gastric Ulcer."

TEXAS

Society News—Dr. Paul C. Williams, Dallas, addressed the Grayson County Medical Society, Sherman, recently on "Lesions of the Lumbosacral Spine"—Drs. Nellius C. Smith, Hillsboro, and Otto G. Zacharias, Whitney, addressed the Hill County Medical Society, Hillsboro, recently on "Serum Treatment for Lobar Pneumonia" and "Sulfanilamide Therapy," respectively—Drs. Louie E. Allday and Cecil O. Patterson, Dallas, addressed the Titus County Medical Society, Mount Pleasant, February 8, on "Therapy of Pneumonia with Especial Reference to the Various Serums Used" and "The Medical and Dietetic Management in Acute Cholecystitis," respectively—Drs. Simeon H. Hulsey and William L. Howell, Fort Worth, addressed the Brown-Mills-San Sabá Counties Medical Society, Brownwood, January 10, on "Bronchiectasis" and "Diagnosis of Heart Conditions" respectively—Drs. Harold L. D. Kirlham and Edwin Ghent Graves, Houston, addressed the Jefferson County Medical Society, Port Arthur, January 10, on "Facial Injuries" and "Recent Advances in Internal Medicine" respectively—Dr. Byron A. Jenkins, Lubbock, addressed the Lubbock-Crosby Counties Medical Society, Lubbock, January 4, on "The Infant's Diet During the First Year"—A symposium on sulfanilamide therapy was presented at a meeting of the Tarrant County Medical Society, Fort Worth, January 4, by Drs. Horace S. Renshaw, Douglas G. Mitchell, Craig W. Munter, Thomas H. Thomason and Sidney E. Stout, all of Fort Worth.

PHILIPPINE ISLANDS

Personal—Dr. Eusebio D. Aguilar, Manila, has been appointed director of the bureau of public welfare for the islands—Dr. Gregorio Lantín, Manila, has been made head of the medicolegal section of the department of justice.

University News—The board of regents of the College of Medicine, University of the Philippines recently abolished the medicolegal department of the school. Srato de los Angeles, L.M., head of the department since its establishment, has resigned.

GENERAL

Scholarship in Psychiatry—The Institute of International Education announces that a Woolley scholarship in Paris is offered to a student in psychiatry for the year beginning October 1. The scholarship consists of \$600 and a room in the United States House of the Cité Universitaire in Paris, under whose auspices the offer is made. To qualify, a candidate must be an American citizen, hold a medical degree or be in the last year of study for it, be under 30 and unmarried and have a good working knowledge of the French language. For application blanks apply to the Institute of International Education, 2 West Forty-Fifth Street, New York.

Academy of Arts and Sciences to Award Septennial Prize—Announcement is made of the "Francis Amory Septennial Prize" to be awarded by the American Academy of Arts and Sciences for "outstanding work with reference to the alleviation or cure of diseases affecting the human genital organs." The fund providing the award was a gift of the late Francis Amory, Beverly, Mass. It will amount to more than \$10,000 and may be given in one or more awards, the first in 1940 if work of a quality to warrant it is presented. There will be no formal nominations, and no formal essays or treatises will be required. Suggestions should be made to the Amory Fund Committee, 28 Newbury Street, Boston.

New President of Parke, Davis & Company—Dr. Alexander W. Lescohier, Grosse Pointe, Mich., was elected president of Parke, Davis & Company at a meeting of the board of directors in Detroit March 1, to succeed Oscar W. Smith, who died February 7. Dr. Lescohier has been general manager and a director since 1929. He joined the staff of Parke, Davis & Company in 1909, the year of his graduation from Detroit College of Medicine. In 1918 he was named assistant director of the research and biologic laboratories, where he was in charge of the production of serums, vaccines, antitoxins and other biologic products, in 1925 he was made director of the department of experimental medicine and in 1928 assistant to the president.

The Annual Golf Tournament in San Francisco—The twenty-fourth annual tournament of the American Medical Golfing Association will be held at the San Francisco Golf and Country Club Monday June 13. The association has planned a tour for its members, beginning with an ocean trip from New York to New Orleans and including six games at cities on the way. The group will sail from New York June 1 and play its first game in New Orleans June 7. Games will be played at Houston, Galveston, San Antonio, Los Angeles and Del Monte, Calif. The return trip will be through Portland, Seattle, Vancouver, Lake Louise and Banff, with two more games and a trip up Puget Sound. The president of the association is Dr. Walt P. Conaway, 1723 Pacific Avenue, Atlantic City, N. J., and the executive secretary is Bill Burns, 2020 Olds Tower Lansing, Mich.

Changes in Status of Licensure—The North Dakota State Board of Medical Examiners recently reported the following action:

Dr. John Morgan Phillips, Bisbee, license suspended following charges of having performed an illegal operation.

Dr. Joseph Allaire, Olga, license suspended after his pleading guilty to use of narcotics.

The Commission on Licensure of the Medical Society of the District of Columbia announced the following:

Dr. James D. Eggleston, Takoma Park, Md., license revoked January 21, having been convicted of performing an illegal operation.

The Virginia State Board of Medical Examiners reports the following recent action:

Dr. Robert Clay Hogue, Richmond, license revoked following his conviction of violation of the Harrison Narcotic Act.

The Illinois State Board of Registration and Education announces the following:

Dr. Benjamin McChapman, Chicago, license restored Dec. 21, 1937.

Dedication of Indian Hospital—Dr. William W. Peter, medical director of the Navajo-Hopi Indian Reservations in northeast Arizona, sends a special invitation to physicians attending the annual session of the American Medical Association in San Francisco June 13-17 to attend the dedication of a new base hospital for the reservation at Fort Defiance June 20. Three days of clinics will follow. Those who contemplate visiting the reservation for this occasion should write to Dr. Peter at Window Rock, Ariz., giving expected date of arrival, length of stay and number in party so that reservations can be made either at Gallup, N. M. (the nearest town, 31 miles from Fort Defiance) or in the dormitories at Fort Defiance. Tours over the 25,000 square mile reservation will be arranged on request. Physicians and public health workers in states bordering Arizona are also invited.

Yellow Blackboards

The National Institute of Industrial Psychology has turned aside from its investigations of the working conditions of factories and offices to those of schools and directed its attention to the strain of copying from the blackboard. It has now published an investigation entitled "Improving the Blackboard," by Dr W D Seymour, which may render that time-honored article obsolete. The strain felt by children copying from the blackboard may be partly due to the repeated movements of the head and eyes and to changes of accommodation, but the question arose whether it was also due to copying from a black board on to white paper. The former has a reflection factor of from 10 to 15 per cent while the latter has one of from 85 to 90 per cent. The object of the investigation was to find whether a board with a much higher reflection factor than a black board would enable children to copy from it more quickly and with less strain. As a white board would cause glare, a light yellow board was chosen for the experiments, with blue as the color for the chalk. An instrument was devised to record on a moving tape the time taken by adults to read successively exposed short syllables presented first in white letters on a black board and then in dark blue letters on a yellow board. The words on the yellow board were read more quickly, the average difference being 15.4 per cent. The experiment was then made in the class room of getting children to copy the usual white letters on a black board and comparing the result with copying from a yellow board. The results showed an advantage in time of 10 per cent for the latter. It is suggested that this saving in time represents a material reduction in strain. A further investigation is being made of the most suitable material from which boards of the color found best from the visual standpoint may be constructed.

Medicine and Eugenics

In his Galton lecture to the Eugenics Society, Prof J A Ryle made a plea for greater attention to eugenics. Planning for national health and efficiency should be in the hands of the three great applied sciences—medicine, eugenics and sociology. Medicine, he regretted to say, was so taken up with urgent practical affairs that it had scarcely found time to consider what its true objectives are. Between the three there was at present no true cooperation. It was rare to meet among physicians one with even the rudiments of genetics or more than a superficial interest in the prospect of race betterment by eugenic education or legislation. The Eugenics Society had 650 members, only one fifth of whom were physicians. The membership should be much higher and the proportion of physicians should be increased if any large and effective policy was to come forth. A program to solicit the fuller cooperation of medicine would be more effective than any propaganda to awaken interest in lay audiences. Professor Ryle made the following practical recommendations:

1 A national council should be formed embodying the triple alliance between medicine, eugenics and sociology, with representatives in each instance of the academic and applied sciences and appropriate contacts with the ministries and research departments of health, agriculture and labor. This council should be advisory for education, research in human genetics and social reorganization. It should regularly transmit to the legislative councils of the country the information accumulated, with suggestions for reform based thereon. In the preventive field such a council might stand in the same relation to the government

as the Medical Research Council now stands for the problems of medical research and its application to practice.

2 As part of a general reform in medical education, the curriculum should be modified to lay more stress on all preventive aspects. The preservation of health by nutritional and other social reforms and by applications of human and animal genetic studies to eugenic education and legislation should receive fuller emphasis, both in the preclinical and in the clinical periods. In the clinical period, teachers should recognize a special duty in connection with the prophylactic aspects of medicine.

3 With the help of existing organizations, eugenic and sociologic, an endeavor should be made to interest the physicians of the country, through their medical and scientific societies, in the preventive and educational role which they might themselves fulfil by instruction in domestic eugenics, both positive and negative. The preservation of health as a primary function with the treatment of disease as a secondary function, should become the new ideal.

4 A limited number of research chairs or readerships in human genetics should be established preferably in universities where the medical and biologic services already function side by side.

An Australian Premarriage Clinic

A premarriage clinic has been opened in Sydney, where health tests are available for couples about to marry. The clinic is subsidized by the state government of New South Wales and is sponsored by the Racial Hygiene Association. It arranges an exhaustive overhaul by any of twelve specialists for a nominal fee. It issues certificates that (1) the parties contemplating marriage are fit to marry and raise a family, (2) the marriage should be delayed for from three to six months or (3) the marriage should be permitted without parentage or should be discouraged. The clinic receives letters from young people on marriage problems at the rate of 100 a month.

Sir Thomas Stanton

Sir Thomas Stanton, chief medical adviser to the secretary of state for the colonies and co-discoverer of the cause of beriberi and a pioneer worker on other tropical diseases, died in London. Born in Canada in 1875, he graduated M.D. from Toronto and continued his medical studies in London at University College Hospital and the London Hospital. At the Hospital for Tropical Diseases he became house surgeon to Manson, who appointed him demonstrator. In 1907 he went to the Malay States to assist Henry Fraser, director of medical research at Kuala Lumpur in an attempt to discover the cause of beriberi. They experimented with two groups of coolies who were making a road through virgin jungle. One group was fed on polished rice, the other on parboiled rice. They were thus able to prove that beriberi was due to feeding on rice from which the outer layers had been removed by polishing. They found that the subpericarpal layers contained certain 'alcohol-soluble substances minute in amount but of high physiological value in nutrition.' Thus the important new conception of 'a deficiency disease' entered medicine. It was not until some years later that Funk introduced the name vitamin for such substances. Stanton and Fraser wrote numerous valuable papers on beriberi which were republished in a volume entitled "Collected Papers on Beriberi." He was able to write in the preface, "Beriberi, which was formerly a scourge in the Orient, is now well on the way to extinction." Stanton was also an excellent entomologist and did work on the identification of mosquito larvae almost as important as that on beriberi. He also discovered that an obscure and fatal disease which appeared in 1917 among the laborers on rubber estates was due to an organism like that of glanders. He named the disease 'meloidosis.'

Cevitamic Acid in the Treatment of Addison's Disease

Few reports have appeared on the use of cevitic acid in Addison's disease, although the results of the research of Szent-Gyorgyi justify such a treatment. At the January 21 meeting of the *Société médicale des hôpitaux* a case was reported by Laederich and his associates in which gratifying results followed the use of cevitic acid in Addison's disease. The patient was a male nurse, aged 31, whose chief complaints on admission to the hospital, Sept 9, 1937, were severe asthenia and gastrointestinal disturbances of six months' duration. Examination revealed the typical skin pigmentation found in Addison's disease, especially marked on parts of the body exposed to the air as well as on the buccal mucosa. The asthenia and emaciation were also apparent. The epidermal reaction to tuberculin was markedly positive. The Wassermann reaction was negative. Until October 11 a daily hypodermic injection was given of adrenal cortex extract but the patient's condition showed no improvement. Cevitic acid was then given in doses of 1 Gm daily in a single dose. Within ninety-six hours after this treatment was begun, i. e., as soon as the acid appeared in the urine, a striking improvement was noted in the form of cessation of emesis and diarrhea with return of appetite. The patient was able to get out of bed October 20 and the skin and mouth pigmentation began to lessen until the middle of November, since which time it has remained stationary.

Harris, Ray and Ward have called attention to the fact that delay in the appearance of cevitic acid in the urine of patients suffering from vitamin C subnutrition is an excellent way of evaluating the degree of avitaminosis. This method was applied in the case reported by Laederich and his associates. In spite of the administration of 36 Gm of cevitic acid during the first four days, none of the acid was found in the urine. Similar observations in five cases of Addison's disease have been reported by others. The rapid disappearance of the asthenia, digestive disorders and genital disturbances as in the present case has not been reported previously. The authors consider their case as symptomatically improved following the use of cevitic acid in large doses.

Diagnostic Centers for Low-Income Classes

To avoid the conversion of the medical profession into government officials in the state's effort to socialize medicine, the secretary of the organization which looks after public relations for the profession here proposed about a year ago to establish diagnostic centers all over France. These centers were to be organized by what corresponds to the county medical societies in the United States. The staffs were to be composed of the specialists and general practitioners of each county. The chief objective of each center was to be preventive medicine, in the form of examination of patients referred by local practitioners whose income did not permit payment of the laboratory and specialist fees incidental to the diagnosis of conditions difficult to recognize with the facilities usually at the disposal of the general practitioner. This idea of diagnostic centers was the subject of much discussion at the annual meeting in December 1937 of the *Confédération des syndicats médicaux*, delegates from all of the ninety departments of France taking part. Only one county society had tried such a diagnostic center plan. The secretary of this society reported that quarters had been placed at their disposal by the county hospital. Patients in the low-income class are sent by their attending physicians with a slip indicating that certain examinations ought to be made, some

of which might require the services of specialists. Following a complete study of a given case, the patient is sent back to his physician with the results of the various examinations. No effort is made to treat those in the low-income class, this is carried out only in the case of indigents, for whose care the county authorities pay. Those in the low-income class are charged a fee merely sufficient to pay for laboratory charges.

The Antituberculosis Campaign

Prof Fernand Bezançon read a paper at the February 22 meeting of the *Académie de médecine* of Paris in which he showed how differently pulmonary tuberculosis is regarded at present from what it was twenty years ago. At that period it was believed that the appearance of the disease in adult life was simply a recrudescence of a primary infection in infancy, and hence the objectives of the fight against tuberculosis were to isolate children from possible contagion and to attempt to eliminate any cause which could favor its lighting up in adults. The Pirquet test appeared to show that the number of positive reactions increased with age until they attained 97 per cent in adults. Recent contributions to the subject by American and northern European phthisiologists, confirmed in France, have shown that the statistics of an almost universal positive reaction in adults were based on dispensary observations made among the poorer classes and that in reality if one applies the tuberculin test to those residing but a short time in the larger cities as well as to those in the middle and upper classes of society it would be found that from 30 to 40 per cent of young adults showed a negative reaction. Hence the question arises as to whether a large number of the tuberculous manifestations seen in adolescents and young adults ought not to be considered late primary infections rather than a lighting up of a primary infection in nurslings and young children. It follows that exposure to infection in adults plays a far more important part than any other cause, hence the lesson to be drawn from the observations of Scandinavian phthisiologists is that under no conditions should persons who have a negative tuberculin reaction be permitted to do any work in which they are exposed to contact with tuberculous persons. This applies particularly to medical students and pupil nurses.

Another question is whether it is necessary to separate children showing a positive tuberculin reaction from contact with tuberculous parents. The recent observations of Professor Bezançon and his co-workers (*Negative Tuberculin Skin Reactions in Children*, *THE JOURNAL*, Oct 16, 1937, p 1289) have shown that children exposed to such infection by parents have either curable forms of the disease or only a positive skin reaction or present no evidences of infection.

One of the most important tasks for those interested in the subject, in the near future, is to follow individuals showing either positive or negative reactions when exposed to tuberculous infection.

Early diagnosis not only with the aid of the skin reactions but also by means of radiography and thorough clinical examination is the immediate goal of the fight against tuberculosis. The dispensary must remain the keystone of the arch in this fight, aided by the work of visiting nurses who will supervise home hygiene. The sanatorium ought to become more and more an active treatment center and not to be filled up with patients who really do not need sanatorium care, such as those recovering from a hemoptysis without bacilli in the expectoration, and only discrete radiologic evidence of disease. Also to be excluded are those convalescing from pleurisy, also old fibrous tuberculosis patients and those with chronic bronchitis and emphysema. For the first named preventorium or convalescent homes should be created. The more chronic cases should be cared for in special hospitals for this purpose. The sanatorium should be reserved for cases in active evolution and these patients

should be sent home as soon as the acute stage has passed. Tuberculosis causes more than 60,000 deaths every year in France, and between 500,000 and 600,000 persons here have the disease.

Feb 14, 1938

Investigation of Blood Donors

Dr K. A. Seggel of the Leipzig Medical Society investigated the blood donors of his city. The total number of recorded requests for blood donors was 1,865. Thorough preliminary and subsequent observation of the donor is an urgent necessity; it should include complete serologic examination. In all, 1,042 such examinations were carried out. The total amount of blood donated was 672 liters. The number of donors varied, 195 blood donors' certificates being issued, thirty-two donors had undergone more than twenty transfusions and eight more than thirty. The maximum per donor was thirty-three transfusions. There were forty-five donors who had provided more than 6 liters of blood, ten of whom had given in excess of 10 liters, the maximum was 12 liters. Good medical care of the donor is certainly desirable, since frequently a substitute is difficult to find. There is a steadily increasing demand for blood donors. Formerly only forty-seven transfusions were performed in a quarter, now the number is around 240. The national ministry of the interior regulates the compensation of donors.

Disturbances due to incorrect blood typing of recipients are avoidable, two cases were reported in each of which 400 cc of atypical "incompatible" blood was transfused without untoward clinical consequences. On the contrary, in five cases transfusions of smaller amounts (from 10 to 375 cc) of atypical "incompatible" blood were followed by disturbances: hemolysis, nephritis, and so on. The so-called Oehlerker biologic preliminary test is considered distinctly unreliable. In one case mild clinical symptoms followed transfusion of O blood to an A recipient whose blood had incorrectly been typed as O. Thus far it has been impossible to avoid occasional disturbances even if the blood of donor and recipient is compatible on the basis of the classic fourfold grouping, especially noteworthy incidents in point were four cases of icterus (three of the patients were of group A, one of group AB) and three cases of hemoglobinuria all in group A patients. The majority of recipients in the mentioned cases had tolerated without any incident other transfusions of similar type blood both previously and subsequently. One is surprised to find that these anomalous cases always concerned a recipient of the A type, possibly these phenomena indicate that persons of A₁ type may present an α and persons of A type an α_1 . Such incidents are, however, extremely rare (seven instances, in all, 1,865 transfusions). Prophylaxis by exact evaluation of the peculiarities of the subgroups is virtually impossible in clinical practice.

Improved Cardiac Diagnosis

Prof. A. Weber, Naunheim cardiologist, recently lectured to the Frankfurt Medical Society on improved cardiac diagnosis. He called particular attention to four diagnostic technics.

1. Evaluation of arterial sounds by auscultatory measurement of blood pressure. By the quality of these sounds the magnitude of the cardiac output may be gaged. Arterial sounds are always more distinct under circumstances in which increased cardiac output would be expected after physical exercise, in states of psychic excitation, in aortic insufficiency, after an extrasystole with prolonged compensatory pause and in feverish patients whose hearts are healthy. Subdued arterial sounds are heard under other conditions, e. g., in aortal and mitral stenoses, in collapse and in coronary thrombosis. Intermittent loud and soft arterial sounds accompany the pulsus alternans. A diminution

of the arterial sounds in the febrile stage of infectious disease or in narcosis is an earlier portent of circulatory failure than a fall in blood pressure.

2. Evaluation of the venous pulse. Systemic circulatory stasis leads to premature termination of the systole, a symptom usually present in mitral stenosis. Enlargement of the presystolic waves and simultaneously appearing small systolic waves are also characteristic for mitral stenosis. The manifestation of an "insufficiency wave" which rises with the beginning of the first sound, and which therefore precedes the systolic venous wave, indicates tricuspid insufficiency.

3. Evaluation of the heart sounds. A graphic record of the heart sound curve obtained with proper apparatus represents an objective check on the data elicited by auscultation. Moreover, the heart sound curve provides a whole group of data imperceptible to the most expert auscultatory technics. An example in point would be the soft abnormal sound phenomena that sometimes accompany intense audible sounds. From auscultation one obtains a decidedly incomplete impression of the duration of a sound. In coronary sclerosis, hypertension and so on, highly significant signs such as presystolic murmurs are imperceptible by auscultation. Yet this type of bruit is actually common and is an objective indication of left ventricular failure. Supernumerary sounds, often detected with difficulty by auscultation, nearly always become plainly demonstrable in a correct recording of the heart sounds.

4. Electrocardiography, the technic by which various arrhythmias are evaluated and the diagnostic aid *par excellence* in coronary disease and myocardial lesions both ephemeral and chronic.

The Heritability of Neuropathic Muscular Atrophy

Formerly the term neural muscular atrophy was applied to those forms of progressive muscular atrophy in which the peripheral nerves as well as the musculature undergo degeneration while the cells of the anterior horn of the spinal cord present only insignificant changes, or no changes whatever. But as H. Boeters stated in a lecture before the German Society of Genetics, the degeneration of the peripheral nervous system is not a uniformly present condition, whereas degenerative changes in the cells of the anterior horn and atrophy of the anterior root are always demonstrable. The clinical picture varies in correspondence with the progress of the degenerative processes objectively observed. The disease usually begins in the first or second decade of life and is characterized by a slowly progressive muscle atrophy which attacks various parts of the extremities, especially the calf of the leg. Areflexia, vasomotor disturbances and changes in response to electrical stimuli are also present. In addition to the peripheral changes, some cases are marked by degenerative changes in the gray columns (these cases develop into Friedreich's ataxia). In still other cases, changes in the lateral pyramidal columns are observed. In view of these variations "neural muscular atrophy," a designation that implies a limitation of the process to the peripheral venous system, can no longer be considered correct.

The hereditary transmission of the disorder has not been well understood. Boeters therefore recently undertook pertinent investigation of a total of 1,125 persons in thirty five different families. In addition to the original forty two cases of neuropathic muscular atrophy, which led to the selection of the families studied, Boeters discovered 121 other cases among relatives. In a large majority of cases the disease had been directly transmitted from parents to children over several generations. In a small number of instances the disorder was present in siblings but the parents were healthy. Close investigation of these allegedly healthy parents however, often elicited histories of relatively mild anomalies: talipes cavus, slight atrophy of the musculature of the calf accompanied by

areflexia, complaints of weakness and apparent crippling of a leg on exposure to cold. The foregoing observations indicate that the disease most often is not strongly manifested and the predisposition may accordingly be wholly checked. Still there may persist an (incomplete) dominant transmission coexistent with a relatively slight penetration and active expression of the trait. This observation is corroborated by the morbidity statistics. In the material studied by Boeters the ratio of males affected by neuropathic muscular atrophy to females similarly affected was 2:1 (a ratio in agreement with other data). A sound interpretation of this variation has yet to be made. Besides, it is still problematic whether the female sex exerts an inhibitory influence on the manifestation or whether men as a consequence of stronger demands made on them, namely, more marked environmental influence, are more frequently the victims. In Boeters' material the onset of the disorder lay between the sixth and the twentieth year of life. Great variability was noted with respect to the course and severity of the disease. In fact, certain families presented pluralities of cases so similar, even to minute characteristics, that a sort of familial type of the disease was considered probable. The social value of the patients was extremely diverse. Families in which the disorder was manifested preponderantly or exclusively in a milder form were rare. If the disease began early and progressed the patient did not procreate, on the contrary, a late inception and mild course of the disease did not prevent marriage and procreation. The general course of the atrophy is severe and in Boeters' opinion justifies sterilization of the sufferer, provision for which is made in the German law.

Jan 25, 1938

Plumbism Among Cigar Makers

Following the official report of forty-one cases listed as lead poisoning among the employees of fourteen cigar factories in the southern part of the country, an inquiry was inaugurated by the medical service of the factory inspection bureau. More than half of these cases and other cases subsequently reported were characterized by gingival lines. There were also a number of suspected cases. The inquiry was principally concerned with the underlying cause of these accidents. Three possible sources of contamination were considered: (1) the sheets of zinc on which the cigars are cut (cf. Pel's case, *Zentralbl f inn Med* 18:545, 1897), (2) the factory drinking water and (3) the drinking water in the homes of workers affected. A combination of these sources was thought to underlie some cases. The respective importance of the mentioned factors was regarded as unequal, the water, which in many instances was pumped from wells, was considered of greater significance than the zinc sheets. The health authorities have advised the various community governments and the public at large that for the time being there ought to be a revival of the old well bucket or at least a rejection of the first water to issue from the pump. This first flow of water, so commonly used in preparation of the morning coffee, probably will have stood all night in the leaden pipe.

Care of the Babies of Unmarried Mothers

Dr. Knapper investigated the type of care received at present by the babies of unmarried mothers in the Netherlands. One organization, the Federation of Maternity Homes for the Unmarried Mother, is exclusively devoted to this problem. There are forty-seven such institutions under public control and many others under private auspices. Knapper concluded from his observations that the problem is far from being satisfactorily solved. The author places special emphasis on the following conditions which call for amelioration: buildings often

antiquated, crowded and poorly ventilated, financial resources insufficient to permit the mothers to suckle their babies during the first three months, poorly trained nursing personnel, unhygienic conditions that inevitably breed epidemics. Dr. Knapper suggests that proper care of the unmarried mother ought to be assured by law.

Tuberculosis Mortality in the Netherland East Indies

Whereas, according to official statistics of the Netherland Indies, the mortality from paludism was only 5 per cent, that of typhoid 4 per cent, that of dysentery 3.5 per cent and that of cancer 3 per cent, the death rate from tuberculosis was 13.5 per cent. The last named disease thus claims more victims than all the other mentioned maladies together. It is important therefore to determine which elements of the population are chiefly affected by tuberculosis.

Data from the Tuberculosis Center at Surabaya and the sanatorium at Batoe indicate an equal morbidity from the disease in all elements of the population. At the Surabaya center 1,534 patients were examined in the year 1916, of these, 75 per cent were native, 15 per cent Chinese and 10 per cent European. Of a similar clinical material at the Batoe sanatorium 47 per cent were native, 34 per cent Chinese and 19 per cent European. If one considers that the average native is loath to visit a center and *a fortiori* to be hospitalized, it follows that the morbidity from tuberculosis among the indigenous population must be extremely high.

Queen Wilhelmina Institute of Leprosy Research

The Queen Wilhelmina Institute, although it treats leprosy patients in its hospital wards and dispensary, is primarily a research institution. The plant is divided into two sections in the first are housed the laboratories, the experimental animals, the services of photomicrography and photomacrography, the library and so on, the second section contains the hospital wards (which are carefully arranged in accordance with the studies to be made and treatment to be administered) and the isolation units. The institute is directed by Dr. Lampe. Associated with him is Dr. Lobel, bacteriologist and veterinary. Here, for the first time in the history of leprosy research, veterinary medicine forms an integral part of the medical-scientific approach.

At the first Netherland Indies Congress on Leprosy, many papers were read and discussed. The committee stressed the importance of the problem in question and announced that similar congresses would be held at regular intervals in the future.

Marriages

ELBERT ALEXANDER MACMILLAN, Winston-Salem, N. C. to Miss Nora Irene Frantz of Clymer, Pa., in Philadelphia, Dec 6, 1937.

J. PHELPS HAND JR., Washington, D. C., to Miss Lida Lee Gregg of Marietta, Ga., in Baltimore, Dec 29, 1937.

DAVID WALLACE MACKENZIE JR., New York to Miss Kathryn Byers of Fort William, Ont., Canada, in February.

CHARLES G. HILL, Philadelphia to Miss Caroline Catherine Stump of Irwin, Pa., Dec 24, 1937.

JOSEPH J. MILLER, Pittston, Pa., to Miss Helen Corlyn Ross of Wilkes-Barre, Dec 16, 1937.

ROLAND P. WILDER to Miss Dorothy E. Reeves, both of Malden, Mass., Oct 27, 1937.

PAUL L. WOLPERT, Onawa, Iowa, to Miss Katherine Block of Sioux City, February 10.

JOSEPH F. ROTH to Miss Belva Gibbons, both of Wilkes-Barre, Pa., Dec 13, 1937.

GEORGE D. OLIVER, Quesnel, B. C., to Miss Louise Clunness, Dec 2, 1937.

Deaths

Michael Anthony Burns ☉ Philadelphia, Jefferson Medical College of Philadelphia, 1907, professor of neurology since 1934 at his alma mater, and served successively as demonstrator, lecturer, associate, assistant professor and associate professor, visiting neurologist to the Philadelphia General Hospital, neuropsychiatrist to St. Mary's Hospital, consulting physician to the Institute for Mental Hygiene of the Pennsylvania Hospital, consultant neurologist to St. Joseph's Hospital and attending neurologist to Jefferson Hospital, served during the World War, aged 53, died, March 7, of heart disease.

Thomas Herbert Patton, Tuscaloosa, Ala., Tulane University of Louisiana Medical Department, New Orleans, 1912, member of the Medical Association of the State of Alabama, fellow of the American College of Surgeons, aged 53, on the staffs of the Veterans Administration Facility and the Druid City Hospital, where he died, January 19, as the result of injuries received in a fall from a window.

Sherman McKenney, Fremont, Ohio, Detroit College of Medicine, 1892, served during the World War, formerly county coroner and county health officer and member of the school board, on the staffs of the Community Hospital and the Memorial Hospital, aged 70, died, January 16, of coronary occlusion, while aboard the *S. S. Mariposa*, en route to San Pedro, Calif., on a cruise to Australia.

George H. Penrose, Col. Q. M. C., U. S. Army, Washington, D. C., University of Buffalo School of Medicine, 1886, veteran of the Spanish-American War, served in the quartermaster corps of the army in various capacities, in 1920 was made a colonel, and retired in 1922 at his own request after twenty-four years service, aged 76, died, January 6, in the Walter Reed General Hospital.

Luther Hess Hamilton ☉ Portland, Ore., Jefferson Medical College of Philadelphia, 1901, member of the North Pacific Surgical Association, fellow of the American College of Surgeons, at one time assistant clinical professor of surgery at the University of Oregon Medical School, on the staff of the Good Samaritan Hospital, aged 64, died, January 16, of cerebral hemorrhage.

James A. Pickett, El Paso, Texas, Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906, member of the State Medical Association of Texas, past president of the El Paso County Medical Society, on the staffs of the City-County Hospital and the Hotel Dieu, Sisters Hospital, aged 55, died, January 27, of peritonitis following an operation.

Hermann Feit ☉ New York, Rheinische Friedrich Wilhelms-Universität Medizinische Fakultät, Bonn, Prussia, 1919, dermatologist to the Vanderbilt Clinic, Columbia University, Englewood (N. J.) Hospital, Greenville Hospital, Jersey City and the New York Skin and Cancer Hospital, aged 47, died, January 18, of a malignant growth.

William August Engsberg, Lakemills, Wis., Rush Medical College, Chicago, 1891, member of the State Medical Society of Wisconsin, at one time mayor of Lakemills, bank president, aged 70, died, January 18 in the Madison (Wis.) General Hospital, of pulmonary embolism and hypertrophy of the prostate.

John Walker Hauxhurst, Bay City, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1876, member of the Michigan State Medical Society, past president of the Bay County Medical Society, on the staff of the Mercy Hospital, aged 89, died, January 22, of cerebral hemorrhage.

Bradley A. Fowler, Brownwood, Texas, Vanderbilt University School of Medicine, Nashville, Tenn., 1888, member of the State Medical Association of Texas, formerly on the staffs of the Medical Arts Hospital and the Stump General Hospital, aged 72, died, January 29, of coronary thrombosis.

Russell Park Glenn, Abilene, Texas, Atlanta College of Physicians and Surgeons, 1905, fellow of the American College of Surgeons, on the staff of the West Texas Baptist Sanitarium, member of the State Medical Association of Texas, aged 64, died, January 2, of coronary occlusion.

Marie Louise Chard ☉ New York, Woman's Medical College of the New York Infirmary for Women and Children, New York, 1895, fellow of the American College of Surgeons, on the staff of the New York Infirmary for Women and Children, aged 70, died, January 20, of myocarditis.

Frank L. Magoon, St. Louis, St. Louis College of Physicians and Surgeons, 1892, member of the Missouri State Medical Association, past president of the board of education, and formerly vice president of the board of police commissioners, aged 70, died, January 17, of heart disease.

Mary Bunker Jepson ☉ Olean, N. Y., Hering Medical College, Chicago, 1895, past president of the Cattaraugus County Medical Society, on the staff of the Olean General Hospital, aged 70, died, January 2, in Miami Beach, Fla., of chronic lymphatic leukemia.

Peter D. Bixel ☉ Pandora, Ohio, Eclectic Medical Institute, Cincinnati, 1901, formerly county coroner, president of the county board of health, on the staff of the Bluffton (Ohio) Community Hospital, aged 72, died suddenly, January 2, of coronary thrombosis.

Pierre Hoa Le Blanc, New Orleans, Tulane University of Louisiana Medical Department, New Orleans, 1894, medical examiner for the Life Insurance Company of Virginia, aged 69, died, January 4, of chronic myocarditis and coronary thrombosis.

John Elmer Hammer, Kiowa, Kan., University Medical College of Kansas City, Mo., 1913, member of the Kansas Medical Society, served during the World War, aged 48, died, January 2, in a hospital at Wichita, of auricular fibrillation.

Lachlan MacLean Beatson ☉ Arkansas City, Kan., University College of Medicine, Richmond, Va., 1908, served during the World War, for many years member of the board of education, aged 54, died, January 2, of angina pectoris.

Andrew J. Crawford, Glouster, Ohio, College of Physicians and Surgeons, Baltimore, 1887, member of the Ohio State Medical Association, formerly member of the state legislature, aged 75, died, January 11, of arteriosclerosis.

Carl James Emmerling ☉ Pekin, Ill., University of Illinois College of Medicine, Chicago, 1926, on the staff of the Pekin Public Hospital, aged 37, died, January 23, in the Proctor Hospital, Peoria, of carcinoma of the lung.

Joseph Edward Honore Garand, Dayton, Minn., School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1899, aged 63, died, Dec. 12, 1937, of bronchopneumonia and diabetes mellitus.

Charles Edwin Jenkins, Brookfield, Mo., Rush Medical College, Chicago, 1900, member of the Missouri State Medical Association, veteran of the Spanish-American and World wars, aged 67, died, January 29, of cerebral hemorrhage.

Martha Estelle Hixson, East Lansing, Mich., Grand Rapids Medical College, 1907, formerly a member of the board of education of Grand Ledge, aged 70, died, January 1, in Haslett, of cerebral hemorrhage and hypertension.

Mary E. Hagadorn, Pasadena, Calif., University of Southern California College of Medicine, Los Angeles, 1892, member of the Associated Anesthetists of the United States and Canada, aged 80, died, January 4, of chronic myocarditis.

Ralph Dart ☉ Rock Island, Ill., Rush Medical College, Chicago, 1903, past president of the Rock Island County Medical Society, at one time health commissioner, aged 57, died suddenly, January 15, of coronary occlusion.

William Thomas Heffernan, Spring Valley, Calif., Medical College of Ohio Cincinnati, 1889, member of the California Medical Association, aged 78, died, Dec. 30, 1937, of cerebral hemorrhage and bronchopneumonia.

Beresford Harty Thompson ☉ Brooklyn, Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1908, served during the World War, aged 52, died in December 1937, in St. John's Hospital of coronary thrombosis.

Benjamin B. Griffith, Vincennes, Ind., Jefferson School of Medicine, Louisville, 1882, Missouri Medical College, St. Louis, 1884, member of the Indiana State Medical Association, aged 75, died, January 16, of coronary occlusion.

Shubel M. Moulton, Minneapolis, University of Louisville (Ky.) Medical Department, 1892, Northwestern University Medical School, Chicago, 1893, aged 71, died, January 22, in the Swedish Hospital, of lobar pneumonia.

Edwin R. Hickerson, Moberly, Mo., St. Louis Medical College, 1885, member of the Missouri State Medical Association, on the staff of the Wabash Employers' Hospital, aged 76, died, January 4, of coronary thrombosis.

Louis Mackler ☉ Atlantic City, N. J., Jefferson Medical College of Philadelphia, 1917, served during the World War, aged 42, was drowned January 11 near Bel Air, Md., when his car skidded and went into a stream.

Simon Gurewitch, Chicago St Louis College of Physicians and Surgeons, 1917, Chicago Medical School, 1922, aged 56, died, January 24, in the Michael Reese Hospital, of generalized peritonitis, secondary to cholecystitis

William Edgar Othello Johnson, Madison, Mo., Louisville (Ky) Medical College, 1884 for many years county coroner, aged 81, died, Dec 3, 1937, in the McCormick Hospital, Moberly, of chronic nephritis

Ira Wilson Ellis, Murphysboro, Ill., Medical College of Indiana, Indianapolis, 1883, formerly mayor, aged 79, on the staff of St Andrew's Hospital, where he died, January 20, of carcinoma of the ascending colon

Jacob Frederick Stock, Woodbury, Pa., Jefferson Medical College of Philadelphia 1890, aged 83, died, Dec 4, 1937, in the Nason Hospital, Roaring Spring, of bronchopneumonia, chronic nephritis and myocarditis

Henry M. Allen, Leesville, La., College of Physicians and Surgeons, Dallas, Texas, 1907, parish coroner, aged 59, died, January 21, in the Baptist Hospital, Alexandria, of encephalitis, influenza and bronchopneumonia

Paul Sheldon Scholes, Canton, Ill., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898, served during the World War, aged 67, died, Dec 9, 1937, of paralysis agitans

Reuben Hills Bemish, Darien, Conn. University of Pennsylvania Department of Medicine, Philadelphia 1887, aged 71, died, January 8, in the Stamford (Conn) Hospital, of myocarditis and arteriosclerosis

Harry B. Carty, Greemansburg, Pa., Medico-Chirurgical College of Philadelphia 1899, member of the Medical Society of the State of Pennsylvania, aged 60, died, Dec 9, 1937, of nephritis and hypertension

Archibald Armstrong Livingston, Cedar Hill, Mo., St Louis College of Physicians and Surgeons, 1907, aged 66, died, January 16, in the Rosiclare (Ill) Hospital, of arteriosclerosis and cerebral hemorrhage.

James Maxwell Ware, Magnolia, Texas (licensed in Texas, under the Act of 1907), member of the State Medical Association of Texas, aged 60, died, Dec 20, 1937, of carcinoma of the liver and intestine

Charles H. Kaiser, Hillsboro, Kan., Kansas Medical College Medical Department of Washburn College Topeka, 1900, member of the Kansas Medical Society, aged 64, died, January 2, of coronary occlusion

John J. Bethea, Hattiesburg, Miss., Tulane University of Louisiana Medical Department, New Orleans, 1889, aged 74, died, January 24, in the Methodist Hospital, of metastatic carcinoma of the lung

Charles Obra Cron, Camp Douglas, Wis., College of Physicians and Surgeons, Keokuk, Iowa, 1896, member of the State Medical Society of Wisconsin, aged 65, died, January 2, of coronary disease

Alvah Graves Ray @ Jackson, Ohio, Kentucky School of Medicine, Louisville 1894, member and past president of the city board of education, aged 70, died, January 19, in an automobile accident

Arthur Spencer Ayres, Indianapolis University of Vermont College of Medicine, Burlington, 1888, member of the Indiana State Medical Association, aged 74, died, January 19, of pneumonia

Thomas Edward Horner @ Atchison, Kan., Kentucky School of Medicine, Louisville, 1897, aged 62, on the staff of the Atchison Hospital, where he died, January 16, of coronary thrombosis

Robert Beatty Castree, Ballston Spa, N. Y., Albany (N. Y.) Medical College, 1901, for many years county coroner and jail physician, aged 61, died, Dec 28, 1937, of coronary thrombosis

Frederick J. Burgess, Hot Springs National Park, Ark., College of Physicians and Surgeons Little Rock, 1910, aged 54, died, January 27, of septicemia, acute nephritis and diabetes mellitus

George W. Bromell, Denver, Eclectic Medical University, Kansas City, Mo., 1911, member of the city board of health, aged 69, died, January 23, in Atlanta, Ga., of chronic myocarditis

Henry Bernhardt Weiper, Lower Lake, Calif., Rush Medical College, Chicago, 1884, at one time mayor of Durand Wis., formerly health officer, aged 89, died, Dec 11, 1937, of pneumonia

Clifford Walcott Kellogg, Higganum, Conn., Yale University School of Medicine, New Haven, 1896, aged 76, died, January 31, in the Middlesex Hospital, Middletown, of pneumonia

Charles Barland Hogeboom, Huntsville, Ala., Medical Department of Grant University, Chattanooga Tenn., 1900, aged 60, died suddenly, January 12, of acute dilatation of the heart

Elmer Hoffman, Sharon, Wis. (licensed in Wisconsin under the Act of 1899), aged 74, died, January 28, in the Walworth County Hospital, Elkhorn, of nephritis and chronic myocarditis

George Fellows McCormack, New Orleans, Hahnemann Medical College and Hospital, Chicago, 1906, aged 54, was found dead, January 14, of hemorrhage and shock due to a fall

Louis Edward Madden, Denver, University of Colorado School of Medicine, Denver, 1927, on the staff of St Joseph's Hospital, aged 39, died, January 21, of pulmonary tuberculosis

Frances Margaret Lane, Cody, Wyo., Hering Medical College, Chicago, 1898, member of the Wyoming State Medical Society, aged 59, died, January 19, of influenza and pneumonia

John Peters Rothermel, Reading, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1889, aged 71, died, Dec 6, 1937, of coronary thrombosis and arteriosclerosis

Raymond Hensel, Niagara Falls, N. Y., Albany Medical College, 1913, member of the Medical Society of the State of New York, aged 47, died, Dec 2 1937, of coronary thrombosis

Oscar Frederick Ziegler @ Wildwood, N. J., Hahnemann Medical College and Hospital of Philadelphia, 1921, aged 40, died, Dec 19, 1937, of angina pectoris and valvular heart disease

Agnes Emilie Hansen, Santa Ana, Calif., College of Physicians and Surgeons of San Francisco, 1907, aged 55, died, Dec 19, 1937, of shock and exhaustion due to a crushed chest

Robert Judson Sharp, Columbus, Ohio, University of the City of New York Medical Department, 1883, aged 83, died, Dec 15, 1937, of lobar pneumonia and chronic myocarditis

Lynn H. Parker, Parsons, Kan., Kansas City Hahnemann Medical College, 1914, member of the Kansas Medical Society, aged 51, was killed, January 2, in an automobile accident

William H. Monahan, Jackson, Ohio, Medical College of Ohio, Cincinnati, 1874, for many years county coroner, aged 87, was found dead, January 18, of cerebral hemorrhage

Edgar Henry Howell @ San Francisco, Hahnemann Medical College of the Pacific, San Francisco, 1907, aged 54, died, Dec 30, 1937, of coronary thrombosis and myocarditis

Augustine T. Holcomb, Novi, Mich., Western Reserve University Medical Department Cleveland, 1884, aged 76, died, January 18, in a hospital at Northville, of pneumonia

Walter C. Whiting, West Bridgewater, Mass., Yale University School of Medicine, New Haven, 1881, aged 79, died, Dec 8, 1937, of paralysis agitans and arteriosclerosis

William H. Borget, Buffalo, Toledo Medical College, 1886, aged 80, died, January 12, in the Douglas Memorial Hospital, Fort Erie, Ont., Canada, of Adams-Stokes syndrome

Henry Randolph Garland, Washington, D. C., Columbian University Medical Department, Washington, 1897, aged 81, died, January 2, of arteriosclerosis and myocarditis

Uriah C. Carson, Long Beach, Calif., Cincinnati College of Medicine and Surgery, 1878, aged 82, died, Dec 26, 1937, of carcinoma of the prostate, nephritis and uremia

Walter Lenehan, Standish, Mich., Vanderbilt University School of Medicine, Nashville, Tenn., 1901, aged 60, died, January 17, in a sanatorium at Howell, of pneumonia

Douglas Wallace, Winnipeg, Manit., Canada, Manitoba Medical College, Winnipeg, 1913, aged 53, died, Dec 23, 1937, in the Winnipeg General Hospital, of endocarditis

James T. Eslin, Washington, D. C., Georgetown University School of Medicine Washington, 1891, aged 80, died in January, of accidental illuminating gas poisoning

John Bristol Yates, Denver, Kentucky University Medical Department, Louisville, 1905, aged 60, died, Dec 23, 1937, of myocarditis, pulmonary tuberculosis and nephritis

Thomas Arthur Graven @ Wooster, Ohio, Jefferson Medical College of Philadelphia 1900 served during the World War, aged 67, died, January 24 of myocarditis

Thomas Richards Griffith, Riverside Calif., Boston University School of Medicine, 1898, aged 72, died, Dec 18, 1937, of arteriosclerosis, renal insufficiency and uremia

William A. Brantley, Atlanta Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta 1897 aged 88, died, January 3, of bronchopneumonia and influenza

Robert Long Boling, San Francisco, University Medical College of Kansas City, Mo., 1897, aged 70, died, Dec. 21, 1937, of myocarditis and hypertrophy of the prostate

Robert Rush Goad ♂ Hillsville, Va., University College of Medicine, Richmond, 1911, bank president, aged 53, died suddenly, January 27, of coronary thrombosis

Charles Adolph Erickson, Rockford, Ill., Chicago College of Medicine and Surgery, 1910, aged 60, died, January 24, in St. Anthony's Hospital, of bronchopneumonia

Rufus Henry Finefrock, Prospect, Ohio, Starling Medical College, Columbus, 1896, formerly state senator, aged 67, was killed, January 12, in an automobile accident

George R. Logan, Enterprise, Ky., Kentucky School of Medicine, Louisville, 1890, aged 81, died, January 20, in St. Joseph's Hospital, Lexington, of pneumonia

Joseph Edward Gavin, New York, University and Bellevue Hospital Medical College, New York, 1917, aged 62, died, January 26, in Miami, Fla., of heart disease

William Grant Bird, Fenton, Mich., Detroit College of Medicine, 1895, fellow of the American College of Surgeons, aged 69, died, January 21, of heart disease

Charles Nathan Caton, Wynona, Okla., Vanderbilt University School of Medicine, Nashville, Tenn., 1901, aged 61, died, Dec. 26, 1937, of coronary thrombosis

Patrick E. Mills ♂ Chicago, Northwestern University Medical School, Chicago, 1901, aged 65, died, January 9, in the Mercy Hospital, of carcinoma of the liver

F. Emerson Daigneau, Austin, Minn., University of Vermont College of Medicine, Burlington, 1886, aged 75, died, Dec. 10, 1937, of coronary disease and nephritis

Edward P. Greene, Campbell, Calif., State University of Iowa College of Homeopathic Medicine, Iowa City, 1888, aged 78, died, Dec. 24, 1937, of myocarditis

John D. Leith, McCreary, Manit., Canada, Trinity Medical College, Toronto, Ont., 1894, aged 76, died, Dec. 14, 1937, of bronchopneumonia and arteriosclerosis

Charles W. Day, New York, Hahnemann Medical College and Hospital, Chicago, 1892, Civil War veteran, aged 89, died, January 19, of angina pectoris

Alexander B. Davis, Wilson, Okla., University of Tennessee Medical Department, Nashville, 1893, aged 80, died, January 12, of cerebral hemorrhage

William T. Beebe, Washington, N. C., Howard University College of Medicine, Washington, D. C., 1906, aged 58, died, Dec. 11, 1937, of bronchopneumonia

Alfred Peter Holz ♂ Seymour, Wis., Wisconsin College of Physicians and Surgeons, Milwaukee, 1898, aged 64, died, January 22, of chronic myocarditis

Chauncey David Creviston, Houston, Texas, Starling Medical College, Columbus, 1900, aged 64, died, Dec. 22, 1937, of bronchopneumonia and influenza

Arthur Bryant Moss, Lincoln, Neb., Jenner Medical College, Chicago, 1908, aged 54, died, January 28, of mesenteric thrombosis and hepatic carcinoma

Lewis C. Cowen, Rising Sun, Ind., Medical College of Ohio, Cincinnati, 1874, aged 89, died, January 27, of arteriosclerosis and cerebral hemorrhage

Jackson B. Shepard, Philadelphia, Howard University College of Medicine, Washington, D. C., 1894, aged 68, died, Dec. 27, 1937, of hypertensive nephritis

Naaman Cyrus Miller, Fostoria, Ohio, Western Reserve University Medical Department, Cleveland, 1882, aged 79, died, January 28, of chronic arthritis

Frank Orson Mosher, San Bernardino, Calif., Dartmouth Medical School, Hanover, N. H., 1896, aged 70, died, Dec. 12, 1937, of pulmonary tuberculosis

Francis Fenelon Johnson, San Francisco, Cooper Medical College, San Francisco, 1894, aged 68, died, Dec. 21, 1937, of arteriosclerosis and myocarditis

Lee D. Robinson, Halleck, Mo., Northwestern Medical College, St. Joseph, 1892, aged 78, died, Dec. 23, 1937, in St. Joseph, of chronic myocarditis

Septimus Jasper Kell, Bluefield, W. Va., College of Physicians and Surgeons, Baltimore, 1907, aged 57, died suddenly, January 12, of angina pectoris

Charles Allison Foulks, Kansas City, Kan., Chicago Medical College, 1885, aged 79, died, Dec. 23, 1937, in Compton, Calif., of coronary thrombosis

Charles F. Bassett, Chicago, Chicago Homeopathic Medical College, 1879, aged 87, died, Dec. 19, 1937, in Altadena, Calif., of coronary thrombosis

Lorenzo Dow Latham, Tulsa, Okla., St. Louis College of Physicians and Surgeons, 1896, aged 74, died, Dec. 11, 1937, in Vinita, of lobar pneumonia

Ross Whittaker Loomis, Toledo, Ohio, Toledo Medical College, 1903, aged 57, died, Dec. 22, 1937, of aortic insufficiency and bronchopneumonia

John L. Livingstone, Long Beach, Calif., Michigan College of Medicine, Detroit, 1883, aged 83, died, Dec. 29, 1937, of carcinoma of the stomach

Guernsey Reiner Lurger, Seattle, University of Cincinnati College of Medicine, 1922, aged 40, died, Dec. 26, 1937, of pulmonary tuberculosis

Alfred J. Harris, McAlester, Okla., Missouri Medical College, St. Louis, 1877, Confederate veteran, aged 96, died, January 21, of pneumonia

Thomas Rea ♂ Yreka, Calif., Oakland College of Medicine and Surgery, 1913, aged 57, died, Dec. 1, 1937, of coronary heart disease and aortitis

Ezra Adonis Shippey, Broadus, Texas (licensed in Texas under the Act of 1907), aged 69, was found dead in bed, Dec. 28, 1937, of endocarditis

William S. Brownell, Detroit, Detroit College of Medicine, 1892, served during the World War, aged 69, died, January 24, of coronary thrombosis

Sidney Avery Clark ♂ Northampton, Mass., Harvard University Medical School, Boston, 1891, aged 72, died, January 14, of coronary thrombosis

Hamilton Worth Emanuel, Milnor, N. D., Fort Wayne (Ind.) College of Medicine, 1880, aged 80, died, January 4, of coronary occlusion

Welch Michael Powers, Tacoma, Wash., Creighton University School of Medicine, Omaha, 1934, aged 29, died, January 8, of pneumonia

ABSORPTION OF DRUGS AND POISONS THROUGH THE SKIN

To the Editor—These comments are prompted by the report of David I. Macht's experiments (*The Absorption of Drugs and Poisons Through the Skin and Mucous Membranes*, *THE JOURNAL*, February 5, p. 409). Macht incorporated drugs in fixed fats, observed systemic reactions of the drugs, and concluded "Such experiments revealed that none of the fixed fats carrying potent drugs were absorbed very readily." If writers on this subject would use the word "absorption" only when they refer to absorption of substances into the blood stream, and "penetration" only when they refer to penetration of substances into or through the skin, much confusion and also, sometimes, faulty deductions would be avoided. Macht, of course, is speaking of penetration into the skin, for certainly he would not expect a fixed fat to be absorbed into the circulation through the skin.

Macht believes that his results should have "great practical significance, particularly to dermatologists," but in dermatologic practice the question of penetration is far more important than that of absorption and on this his experiments throw no light, by reason of the fact that penetration cannot be measured in terms of systemic reaction.

EXPERIMENT 1—Into a test tube run a few cubic centimeters of melted lard containing 2 per cent of salicylic acid. Allow it to harden and overlay with a few cubic centimeters of a 20 per cent solution of ferric chloride. Color reaction diffuses quickly throughout supernatant fluid, demonstrating diffusion of salicylic acid into the aqueous ferric chloride solution.

EXPERIMENT 2—Same as experiment 1, but substitute petrolatum for lard. No appreciable diffusion of salicylic acid into the ferric chloride follows.

Assume that when the salicylic acid-lard combination is rubbed on the skin it penetrates to the subcutaneous layer; there follows free release and diffusion of salicylic acid into the constantly flowing aqueous circulation.

Assume that when the salicylic acid-petrolatum combination is rubbed on the skin it penetrates as well as the lard combination; there follows no release and no diffusion into the circulation.

This indicates that two different vehicles may penetrate the skin equally well but show widely different systemic reactions.

Unlike fixed oils, essential oils may conceivably be absorbed directly into the circulation but only to the extent to which they are soluble in water.

EXPERIMENT 3—In a small test tube place 1 cc. of methyl salicylate and overlay with 1 cc. of 20 per cent ferric chloride. A characteristic blue ring forms immediately and color diffuses upward, being quickly discernible throughout the overlying fluid.

This experiment records the diffusion of dissolved methyl salicylate from the oil-water interface. In the experiment this interface is relatively small compared with the total volume of oil. If, however, the 1 cc. of oil is spread over a large area of skin the relative interface area is tremendously increased and further, if one considers that now the water side of the interface is a constantly flowing stream, one perceives a possible clue to Macht's experimental observations.

If this is the answer, should it not lead to the conclusion that water itself is the most suitable vehicle? It probably would be were it not for the outer lipocorneal layer, through which water does not pass. It is conceivable that essential oils pierce this barrier more readily than fixed oils, but there is nothing in Macht's experiments to prove or disprove it.

The problem of skin penetration and absorption of substances into the circulation is far more than a mechanical one, it involves many physicochemical and biologic considerations as varied as the substances with which one deals. Not until these problems have been solved will the local treatment of skin disorders be placed on a really rational basis.

Take, for example, the official boric acid ointment, with which I have experimented.

EXPERIMENT 4—Saturate a strip of blue litmus paper with water, place on a glass slide and cover with boric acid ointment, U. S. P. Observe the reverse side for the action of boric acid on the blue litmus paper, which should turn pink. After several hours the paper is still blue, showing that there has been virtually no penetration of boric acid into the moist litmus paper.

It can rationally be deduced that when this ointment is used on wounds or ulcers and on those skin disorders in which the lesions are bathed in aqueous secretions, it can have little or no effect, at least as far as the boric acid is concerned. However, the petrolatum can be treated to permit ready release of the boric acid.

While petrolatum virtually locks up boric acid, it releases other substances quite readily. It is obvious that intelligent control of this release factor for various vehicles and drugs would be a distinct advance in the local treatment of skin disorders.

My experiments have convinced me that there will probably never be such a thing as a universal ointment vehicle which is better than any other vehicle. On the contrary, I believe that the more the problem is studied the more it will be realized that vehicles should be individualized in accordance with the drugs used, the therapeutic aim, and special needs of the disorder to be treated.

J. J. SEELMAN, M.D., Milwaukee

HIGH HUMAN TEMPERATURE

To the Editor—In *Queries and Minor Notes* in *THE JOURNAL*, February 5, page 461, in a discussion of the highest temperature that the human body can reach and still survive, doubt is expressed as to temperatures higher than 108° F. While testing the efficacy of different anti-scarlet fever serums administered intravenously to patients with scarlet fever at the Willard Parker Hospital during the years 1930-1932, I observed survival repeatedly following temperatures of 107° or 108°, and occasionally after higher ones—in one case even after a temperature of 110° F. Unquestionably more temperatures greater than 108° F. would have been seen if immediate means for their reduction had not been instituted. However, when a temperature of 107° F. was reached, about a degree lower in children, the patient began to get restless and delirious so that drastic antipyretic measures had to be commenced. These consisted of continuous colonic flushing with ice, as milder measures were found to be useless. For example, in one case, alcohol sponges, acetylsalicylic acid, an ice cap and fluids did not reduce the temperature but on the contrary it kept on rising till it reached 109° F., when the patient died. The patient who had a temperature of 110° F. was given continuous colonic flushing with ice for twenty minutes but the temperature was still 108° in the axilla, 107° after a half an hour, and 102° F. at the end of forty-five minutes, when the treatment was discontinued. In the morning, which happened to be six hours later, the temperature was normal and remained normal until the day of discharge, with the patient showing no ill effects from having been at the point of death. These were elevated temperatures for short periods which usually came about an hour following the administration of the antitoxin and in the majority of instances were preceded by a chill, although the patient with the temperature of 110° F. did not have a chill. In order to prevent any tragic end, the onset of these temperatures had to be watched for carefully. How-

ever, if they were promptly treated no harmful results were observed. These were all rectal temperatures. Thus, the human body can survive a temperature of 110 F and possibly even higher for a short duration and not suffer any discernible adverse consequences.

FERDINAND G. KOJIS, M.D., New York

TESTOSTERONE PROPIONATE

To the Editor—In view of the unwarranted and apparently nation-wide publicity that our paper which was read before the local medical society the other evening received, we think it expedient to publish this statement.

We gave a preliminary report concerning our studies with testosterone propionate before the Baltimore Medical Society on the evening of March 4, and an entirely erroneous newspaper report has spread throughout the country. Our paper reported only a part of our work on patients with hypogonadism, either primary or due to castration. In these the results were very promising. We made no reference to rejuvenating senile men or men with psychic impotence and that sort of condition. However, it seems that an entirely wrong interpretation has been taken by the press reports, and we feel that physicians who have not used this drug should be made aware that we have used enormous dosages, which are not yet practical for routine purposes in other fields that our work is entirely experimental and preliminary and that there is no occasion for any widespread use as yet among the members of the medical profession. It is most unfortunate and regrettable that the public and the members of the medical profession should have their attention called to an apparently valuable drug in such a manner.

As you are probably aware, the development of testosterone is not original on our part, and there are other clinics, both here and abroad, that are making the same clinical observations. We regret exceedingly that our report before the local medical society was misinterpreted.

SELENIUM POISONING

To the Editor—In your issue of Dec. 25, 1937, under Current Comment you report on the retention and elimination of selenium in an article by M. I. Smith, B. B. Westfall and E. F. Stohlman Jr. (*Pub. Health Rep.* 52:1171 [Aug. 27] 1937). By implication one may infer that interruption of ingestion of selenium is followed by its removal from the system and cessation of injury.

The paper by Dr. Hazel E. Munsell, Grace M. DeVaney and Mary H. Kennedy indicates that such injury persists even though the selenium is removed from the animal body. Also it shows rather conclusively that organic selenium is of the same order of toxicity as sodium selenite. This is also shown by the work of the late Dr. Kurt Franke of South Dakota and his associates. A summary of the data along this line is given in Bulletin 311, Alkali Disease or Selenium Poisoning, by Alvin L. Moxon of the South Dakota Agricultural Experiment Station, Brookings, S. D. (1937). Unfortunately I have no extra copy of this paper to send you.

We have abundant information through our work to indicate the probability that organic selenium in green plants is fully as toxic or at least as quickly available as inorganic selenium.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

HEALTHY CHILD OF SYPHILITIC PARENT

To the Editor—A woman aged 46 married has syphilis contracted at 23 years of age and untreated until the present time. A son aged 19 has a positive Wassermann reaction, Hutchinson's teeth and syphilitic iriditis. He is under treatment at present. A daughter aged 10 has negative Wassermann and Kahn reactions on repeated tests and after a provocative injection of arsphenamine. I have discussed the negative reaction of this girl with several competent syphilologists and they are divided as to the necessity of antisyphilitic treatment. Is it possible that this young girl is entirely free? Kindly advise me what course to adopt in this case.

M. D. Quebec

ANSWER—The evidence offered with regard to the 10 year old daughter indicates that the child does not have congenital syphilis. The absence of signs of congenital syphilis and the repeatedly negative reactions are sufficient evidence to eliminate the possibility of syphilis even though the mother has syphilis and a brother has the congenital form of the disease. It is not uncommon for the oldest child of a family to have congenital syphilis while the younger children manifest neither clinical nor serologic signs of it. In view of the absence of confirmatory signs in the 10 year old daughter in question there is no need to treat her for syphilis as she probably does not have the disease.

LAUGHLIN TEST FOR SYPHILIS

To the Editor—Is the Laughlin test for syphilis as reliable and dependable as the Wassermann, the Kahn, the Kline, the Mecke, the Kolmer's or any other modern and trustworthy test for syphilis? Is it an office procedure? About how long would it take to execute that particular test for syphilis? What special equipment will be required to perform this test in the office? How much would it cost and where can such equipment be procured? Where can the antigen be obtained for the performance of the Laughlin test, what is its price? How long will it keep without spoiling? What is the technique of the Laughlin test for syphilis? In the case of inaccessible veins occasionally encountered in obese individuals or infants and others can blood be drawn for that test from either a finger or the lobe of an ear or must it necessarily be drawn from a vein?

ENILIO L. HERGERT, M.D., Brooklyn

ANSWER—The questions raised in this letter are of considerable importance, particularly in connection with present day interest in campaigns against syphilis. Instead of answering these questions directly, it may be well to ask: When may a test for syphilis be considered trustworthy? Until recently it was assumed that for a new test to gain a foothold it must be subjected to trials in many different laboratories and as indicated by numerous publications most of these trials must lead to satisfactory results. The Kahn test, for example, was described in its present form in 1923, yet not until 1928 when the test was demonstrated at the League of Nations Conference at Copenhagen did the test begin to gain recognition and during that year, Kahn listed nearly 250 references to this test. Now, however, the publication of a new method or modification attracts almost immediate interest. This fact, however, does not mean that a new and relatively untried method may safely be used as a diagnostic agent for syphilis. Indeed during the past several years an author of a new method or modification has been having an excellent opportunity to prove the worth of his particular test by including it in the Evaluation Studies of Tests for Syphilis carried on yearly by the United States Public Health Service. These studies throw light not only on the specificity and sensitivity of a given test but also whether or not this test compares favorably with the more established American tests.

The Laughlin test was described in the *Canadian Medical Association Journal* (33:179 [Aug.] 1935) and Robinson and Stroud spoke of it favorably in a note in *THE JOURNAL* (April 3, 1937, p. 1170), claiming 93 per cent agreement with the Wassermann test and 97 per cent agreement with the Kahn test. The test utilizes Kahn antigen to which has been added balsam and a dye. A drop of the antigen reagent is mixed with a drop of serum on a slide and the results are read by means of the microscope. The Laughlin antigen with full directions for its use may be obtained from the Lederle Laboratories of New York, which has been advertising the test as an office procedure. Actually with the present-day availability of private, hospital

and public health laboratories, there seems to be no excuse for physicians to perform tests for syphilis in their office in connection with their practice. A laboratory method is of clinical value provided the method is of established reliability and is performed by one who is expert in the particular method. Many might add a third condition, namely, that the one who performs it should not be familiar with the clinical diagnosis, if any. If a physician has a strong feeling that the clinical diagnosis in a given patient is syphilis, he may not be psychologically fit to read the result of a test on the blood serum of the patient.

Blood may be obtained from a finger or ear lobe for practically all available tests for syphilis.

PURULENT DISCHARGE FROM NIPPLE AND CANCER

To the Editor—Several patients with large breasts and inverted nipples discharging purulent material have recently consulted me. Is this a contributing cause of cancer of the breast? What can be done for these patients?

M D California

ANSWER—It is important to decide whether the purulent material actually comes from the nipple or whether it is simply an accumulation on the depressed nipple. Not infrequently when a nipple is below the surface of the breast, especially in women with large, fat breasts, foreign material such as perspiration or dirt may accumulate in the depressed area and result in a purulent discharge. This is especially true if women do not take particular pains to cleanse these inverted nipples properly. Hence the nipples should be elevated and gently squeezed to see whether the purulent material actually escapes from the ducts. If the purulent matter is due only to lack of sufficient cleanliness, the treatment is simple and the prognosis good. If, however, the purulent material comes from the ducts in the nipple it is essential to rule out the presence of cancer. A purulent discharge in the breast rarely causes cancer. On the other hand, it may often be caused by cancer. An examination of the breasts with the Cutter lamp or by an ordinary roentgenogram may be of assistance. The treatment of these purulent discharges should first be conservative. That is, hot moist dressings should be applied from time to time and also dry heat. If the discharge does not subside under this conservative management it is advisable to incise the involved area. If an abscess is encountered incision is the proper treatment anyway. If a carcinoma is found, a radical operation must be performed immediately. Hence at the time of the exploratory incision, the operating room must be ready for a biopsy and radical operation.

AGRANULOCYTOSIS FROM AMINOPYRINE

To the Editor—In the April issue of *Consumers Union* there is an article on Aminopyrine. Will you kindly inform me whether the use of this drug is as dangerous as this article indicates.

W ALLEN GRIFFITH M D Berwyn Md

ANSWER—The query can be answered by stating that in the light of present knowledge the information in the article mentioned is essentially correct.

Certain points relative to the role of aminopyrine and other drugs in the production of agranulocytosis bear repeated emphasis. First, it is now generally accepted over the world that aminopyrine and its many combinations, including both proprietary and patented remedies for the relief of pain, are capable of producing agranulocytosis in an occasional person, presumably one that is sensitive or "allergic" to the drug. The nature of the sensitivity is not known. Furthermore, it is believed that a large amount of the drug is not necessary to produce depletion of the neutrophilic white cells. Apparently in an occasional patient this may result from only one or two doses of as little as 5 grains (0.03 Gm) each. However, it seems that most cases develop after the long continued use of the drug.

Aminopyrine is an excellent pain relieving agent and for this reason it has been used as the essential ingredient in many patented remedies that are sold to the public without any indication as to its presence. Because of this, the disease still is seen mainly in persons who resort to self medication and purchase such remedies from drug stores. A list of some of these preparations was given by Kracke and Parker in *THE JOURNAL*, Sept 21, 1935 page 960.

Physicians now use aminopyrine with caution, usually accompanied by careful checking of the blood picture. Because of this the disease has apparently decreased markedly from the high peak of more than 1,500 deaths in the United States alone in the three years that ended in 1934. It would appear that it is not safe to use aminopyrine and its combinations under any conditions, since there is the ever present chance that the patient may be sensitive to the drug and, since the disease often develops abruptly and the white cells are depleted before it is

recognized clinically, the use of the drug is always fraught with danger. It should be pointed out that there is evidence incriminating other drugs as etiologic agents in this disease. Most noteworthy of these is dimetophenol, widely used as a fat reducing agent. Also in rare instances the disease can follow the use of arsphenamine and other organic arsenical compounds. Safe rules for physicians to follow are to refrain from the use of aminopyrine and dimetophenol, so far as possible, if it is necessary to use them, the white cell count should be carefully checked at frequent intervals, patients should be cautioned against the purchase of these drugs and any other pain-relieving remedy on which the formula is not stated, constant activity should be exercised to promote legislation that will prohibit the unrestricted sale of such agents to the public. It seems likely that as long as these drugs are available for public consumption there will be agranulocytosis with its high mortality, but that, if they could be dispensed only on prescription, the disease might eventually disappear.

INSULIN IN DIABETES

To the Editor—Moderately severe diabetes is sometimes treated with two doses of insulin (25 units each) given with the morning and evening meals and little or no insulin with the noon meal. A says that little or no insulin is required for the noon meal because the morning dose of insulin continues to act for six to eight hours and so carries over its effect for the noon meal (which should be lower in carbohydrates). B says that the noon meal requires little or no insulin because of the increase in tolerance following the intake of carbohydrates in the morning (the noon meal should be rich in carbohydrates). Please give the correct answer, with reasons also references for further details.

ERWIN R KABACK M D New York

ANSWER—Both answers are partially correct. That the diabetic patient is at his worst in the morning better at noon and best of all in the evening is almost a proverb. In the morning his storage of carbohydrate is low and, as all agree, whether in diabetes or in health that is the time he utilizes carbohydrate least well, at noon and by the night meal increasing quantities of carbohydrate have been brought into action and are being metabolized and in consequence the entire machine is running more normally. Many a diabetic patient can take 10 or 20 Gm of carbohydrate on retiring and wake up sugar free.

The blood sugar, save in the mild cases, which would be ruled out by the premises of the question, is higher in the morning. One would burden it therefore with the least quantity of carbohydrate at a meal and in fact usually this is done by giving one fifth at breakfast and two fifths at each of the other two meals.

Exercise is eliminated at night, so the body begins the day without the advantage of it, but with the progress of the day its favoring influence becomes felt.

But why use regular insulin 25-0-25? Is not the blood sugar of the patient high on rising? Is not a retiring dose of 2, 3 or 4 units required on continued use of regular insulin? With protamine zinc insulin, possibly supplemented by regular insulin, presumably the blood sugar on rising would be nearer normal.

MECHOLYL IONTOPHORESIS IN VASCULAR DISEASE

To the Editor—How efficacious is mecholyl in the treatment of chronic peripheral vascular disease applied by iontophoresis?

M D Massachusetts

ANSWER—The administration of mecholyl (acetyl beta-methylcholine chloride) by means of iontophoresis has been carefully studied for its value in the treatment of all common types of chronic peripheral vascular disease. It has not been found to be efficacious for patients with arteriosclerosis or arteriolosclerosis senilis, or arteriosclerosis with diabetes. It has not been of value in most cases in association with thrombo-angitis obliterans. It has no effect on patients with chronic lymphedema. It is of established value for the healing of chronic varicose and postphlebotic ulcers and has healed many of these following the failure of varicose vein injections and other forms of treatment to heal them. It has a palliative effect in many cases of Raynaud's syndrome, reducing the number and intensity of the attacks but not affecting the course of the disease. In a considerable percentage of cases of scleroderma the course of the disease has been affected favorably, with loosening of the skin and a general increase in local circulation. Accompanying infection and nervous shocks or anxiety apparently prevent improvement in these cases and in some patients there has been unexplained lack of improvement. Patients suffering from mild spasms of the peripheral arterial tree due to trauma such as the group known as "pneumatic

hammer disease," have been relieved of their symptoms in practically all instances by mecholyl iontophoresis.

It should be remembered that in general these conditions are chronic and that improvement from whatever method is inevitably slow. In most instances from thirty to fifty treatments are necessary before judgment as to the value of the method in an individual case can be rendered.

SENSITIZATION TO EPINEPHRINE

To the Editor—Several years ago while having a dental extraction I discovered that I was sensitive to epinephrine. About one year ago I had a foreign body removed from my left eye (cornea) and this was followed by a phlyctenular keratitis. I suffered excruciating pain as these spots appeared on the cornea. This continued until one day my physician said:

This looks like an allergic eye. I then promptly informed him that there was only one thing I was sensitive to and that was epinephrine. He stopped putting epinephrine into my eye and I stopped using phenacaine ointment (which contains epinephrine) and I made a rapid recovery. Since then I have been given an intradermal injection of epinephrine (wheal formation) and within two minutes I had palpitation, trembling, pallor, weakness, a rise in blood pressure of almost 40 mm of mercury and a corresponding rise in pulse. Can a person be desensitized to epinephrine? What is the etiology of sensitization? What is the best procedure to follow?

M D New York

ANSWER—The sensitivity in question may be due to epinephrine, but in view of the fact that many epinephrine preparations contain preservatives this factor should also be considered as a possible causative agent. Not only the different brands vary as to the preservative used but different forms of the same brand frequently contain different preservatives. A great many people are oversensitive to epinephrine and have a lowered threshold to stimulation of the sympathetic system. No method of desensitization to the epinephrine itself is worth undertaking. Frequently such sensitivities are lessened by avoiding fatigue and maintaining good health.

MASTURBATION IN SMALL CHILD

To the Editor—What is the treatment for a 2 year old boy who masturbates? The child has been circumcised. There are no discoverable physical defects.

M D New York

ANSWER—The treatment of masturbating children must begin with the correction of all local disorders in the region of the genitalia. The clothes should be of proper size so that the rubbing of tight clothes does not irritate the penis. Itching skin disorders, such as intertrigo or pediculosis, in the perianal region should be remedied, oxyuriasis (pinworms) if present should be eradicated and so on. Excessive fondling and excitation on the part of parents, servants or older children should be discouraged. Proper emotional balance, physical hygiene and healthful sleeping arrangements should be instituted in the home. Masturbation in a child may be just one manifestation of faulty emotional adjustments resulting from various factors, such as the parents prolonging his infancy by excessive "babying," excessive nagging and punishing, excessive attention and spoiling, or too much emotional excitement in playing with other children. Especially if this is an emotional child, a calm, properly balanced environment is essential. Mechanical restraint is definitely contraindicated. Avoid sending the youngster to bed as a punishment for some misdeed, because having nothing else to do and needing gratification gives impetus to the act. The child should be put to bed at night and for the afternoon nap only when he is tired enough to fall asleep at once, and not allowed to remain in bed in the morning unoccupied for a long time as these are the times when the act is most practiced. During the day his time must be completely occupied by regulating his activities and never leaving him entirely to himself. The habit should not be made the topic of discussion in the presence of the child, nor should punitive measures, such as whipping, shaming, nagging, pleading or bribing ever be used. Nor should he be told that it is dirty or naughty or that the habit will make him sick. A youngster should never be surprised or caught masturbating. When he is found indulging, without referring to the act he should be given some pleasant and interesting task, or invited to play a game which will dis-

tract his attention from the genitalia and interrupt his pre-occupations, in a manner which he has no occasion to resent. Close observation of these children is necessary, but not spying to the extent of arousing fear of being constantly suspected.

It is important to enlighten the family that no great harm will result and that in all probability even if it is ignored and nothing is done, a child of 2 years will sooner or later forget the habit and turn to other forms of amusement, especially if he is otherwise healthy, active and happy.

SWELLING AROUND EYES AFTER SEA BATHING

To the Editor—During the month of August I treated two children both suffering from a marked swelling about the eyes. The upper and lower lids were involved with soft swelling and apparently no inflammation. Both gave a history of having been bathing in the ocean the day before. The condition in each case was treated as one of angioneurotic edema with repeated small injections of epinephrine and cold compresses locally. Both subsided within twelve hours without recurrence. Pain was absent throughout. Am I correct in assuming that these cases were on an allergic basis possibly as reactions to cold sea water?

ATTILIO A. TRIPPISELLI, M.D., Brooklyn

ANSWER—It is not possible from the description to be sure that the diagnosis of angioneurotic edema is correct, although it seems quite probable. Angioneurotic edema is asymmetrical and rarely involves the two eyes at the same time. As to the cause of the swelling, hypersensitivity to cold may well be a factor. Many such cases have been reported and some serious results have occurred in certain patients who are sensitive to cold water. Some even believe that a certain percentage of drownings is due to anaphylactic shock that occurs in patients who are peculiarly hypersensitive to cold. It might be well to try cold applications to the eyes to see if any swelling will result. There is a possibility too that the swelling may be due merely to the irritation to the eyes (not allergic) from the salt contained in water.

COLLECTION AND PRESERVATION OF BLOOD FOR MAILING

To the Editor—Please tell me how to take care of or preserve blood specimens for a Wassermann test. I am obliged to send my work to the state laboratory, and I keep the specimen on ice or in a freezer so that serum is well separated and clear, and then mail it out. During the hot weather, many of my reports from the laboratory show that blood has hemolyzed. What can I do about it?

ERNEST BALL, M.D., Sulphur, Okla.

ANSWER—The collection and preparation of the specimen of blood for shipment to the laboratory are perhaps the most important of the precautions to be taken in securing satisfactory results from serologic tests. Hemolysis is frequently due to the use of unsatisfactory outfits for bleeding. It may result from the retention of solutions if the syringes are sterilized by boiling or even from the force necessary to eject the blood from the syringe into the container. Syringes should not be used unless sterilized by dry heat. The sterilized outfits with Petroff needles are, in general, the most satisfactory and convenient.

In summer, hemolyzed specimens of blood received by mail are often found to be contaminated. A few bacteria that gain access at the time the specimen is collected and that would not render it unsatisfactory for serologic tests if kept for a day or two in the refrigerator or if the work could be undertaken promptly may multiply sufficiently in transit during warm weather to hemolyze the blood. Thus, aseptic precautions should be observed in the collection of blood specimens to avoid contamination, particularly when the specimen is to be subjected to temperatures that favor bacterial growth.

APPARATUS FOR MECOYL IONTOPHORESIS

To the Editor—I am interested in the administration of mecholyl by iontophoresis. Can you suggest where I might obtain the necessary apparatus? Can you also list the necessary parts in making a simple galvanic machine?

M D, Michigan

ANSWER—A simple galvanic machine for administering mecholyl by iontophoresis can be assembled from standard parts obtained from, or through, any radio repair store. The following is a list of the parts: one steel cabinet (Bud No 993), one 50 ma milliammeter (Triplett No 321), one 10,000 ohm variable resistance (Yale E-10M-P) with knob, one ruseholder and three 1/16 ampere fuses, one B battery (Burgess No 5308 for use in cabinet or No 10308 for longer life, or both), one single insulated tip jack, one twin insulated tip jack, 30 feet of braided wire (Kinkless RC), three tip plugs for attaching one end of lead wires to tip jacks, three insulated alligator clips for attaching the other end of the wires to electrodes (2 positive one negative electrode) and two insulated spade lugs for attaching two short wires (2 feet long) to the battery.

Salesman 3 of the Radio Department of M and H Sporting Goods Store, 512 Market Street, Philadelphia, will assemble these parts and supply a convenient wooden brace for holding the battery in place. Makers of other machines for this purpose are the Valverde Laboratories, 252 Lafayette Street, New York, and William Balardo, 3102 Kingsbridge Avenue, Bronx, New York.

PARENTERAL ADMINISTRATION OF IRON

To the Editor—What is the least painful preparation of iron (with strychnine) that can be used for parenteral administration? I have been using Fraisse's Ferrugineous Compound Ampoules (Fougera & Co) but my patients complain of severe pain following injection.

EDWARD GIPSTEIN M.D. New London Conn

ANSWER—The "green iron and ammonium citrates" (now official) is considered the preferable iron preparation for injection purposes, it being claimed that its higher ammonium citrate content as compared with the "iron and ammonium citrates" (of garnet red color) renders it less protein precipitant and therefore its injection less painful. The facts that manufacturers (e.g., Parke, Davis & Co) prefer to market it in ampoules (of 0.015, 0.05 and 0.10 Gm) also containing 0.005 Gm of the local anesthetic quinine and urea hydrochloride, and that it should be given by intramuscular rather than subcutaneous injection, suggest that the problem of painless iron preparation for injection purposes has not yet been solved to entire satisfaction. There is no reason why the desired dose of strychnine nitrate may not be added to the iron solution just before injection. There is, however, no good reason for injecting the strychnine at all, because when the "tonic" effect of strychnine is desired it had better be given in divided doses throughout the day rather than reliance being placed on the effect of an injected single dose that is eliminated from the system within a few hours.

TRANSFER OF UNDULANT FEVER

To the Editor—Are there any records of transfer of undulant fever from one human being to another such as by blood transfusion or by a child nursing?

M.D. Tennessee

ANSWER—Although the possibility of transmitting brucellosis (undulant fever) from person to person does exist, a diligent search of the literature reveals no report of such an occurrence.

DIPHTHERIA CARRIERS

To the Editor—In THE JOURNAL February 5 page 461 is an inquiry regarding treatment for diphtheria carriers. In our service at Bellevue Hospital my associates and I have been called on from time to time to treat diphtheria carriers from the Municipal Contagious Disease Hospital who have been under restraint and medical care without success for long periods. We have administered roentgen therapy and it has proved successful in practically all cases. Our rationale for this treatment is based on the fact that our experience has shown that irradiation causes a fibrosis and shrinkage of tonsillar tissue. While x-rays are not in themselves bactericidal they do favorably affect inflammatory conditions and the endotoxins formed thereby do destroy bacteria. Therefore roentgen therapy is the proper method for destroying the foci harboring tissue of the diphtheria carrier.

IRA I. KAPLAN M.D. New York

BENZEDRINE AND ATROPINE AS CYCLOPLEGIC

To the Editor—An inquiry in the February 26 issue of THE JOURNAL shows misunderstanding regarding the use of benzedrine and homatropine for refraction which might lead to disappointment. McAdams and I use benzedrine both with homatropine and with atropine when those cycloplegics are indicated. The advantage of the combination is that one instillation each of benzedrine with a cycloplegic close together gives approximately the same result as the conventional multiple instillations of the cycloplegic alone with quick recovery. We do not however find it more efficient than prolonged atropinization nor do we space the instillations twenty minutes apart. The report of our experience given at the meeting of the American Academy of Ophthalmology and Otolaryngology is found in the February issue of the *American Journal of Ophthalmology* volume 21 page 121.

S. JUDD BEACH M.D. Portland Me

KOPLIK'S SIGN

To the Editor—On February 1 a patient came to my office with respiratory symptoms. It was necessary to diagnose at once as a measles epidemic was prevalent. On examining the mouth for Koplik's sign of measles I projected the ultraviolet ray (quartz light) into the mouth. I found a very distinct definition of Koplik's sign making diagnosis of measles easy. When I visited the patient two days later the rash had made its appearance. This is apparently the first time this method of diagnosis has been used to bring Koplik's sign out clearly.

Professional Licensure

JOHN KIRKLAND CLARK, New York. One problem which the State Board of Law Examiners in New York is concerned with only most indirectly is the aptitude of the candidate for admission to the profession. This testing is conducted by separate and independent local bodies appointed by the intermediate courts of appeal in the four separate judicial departments of the state, one in New York County, one in the borough of Brooklyn (Kings County) in New York City and the others in Albany and in Rochester. While the unpaid members of the committees on character and fitness are men of high character and ability and devote much time to the problems, they, I believe, would be the first to state that the present method of handling the problem assigned them is not as effective as they would desire. Both doctors and lawyers agree that a man should not be admitted to either profession who is not fitted by personality and temperament to engage in the profession and who has not a character which will enable him to handle successfully and satisfactorily the ethical problems which are bound to confront him. It is obvious from a mere statement of the problem that a board like ours, or a group like the committees on character and fitness, cannot effectively appraise the personalities of the candidates for admission, as to their character content, with anything like the accuracy with which mental abilities can be appraised.

However accurate we have become or may become as to the appraisal of mentality, the work of professional licensure must continue to be unsatisfactory until some more successful method of appraising the character elements in personalities becomes developed into a readily applicable technic. In mental appraisals we can make use of definite types of questions—the propounding of long and intricate problems, writing of essays, the use of "true-false" or short form questions. Would that we could devise some equally efficient system for the appraisal of moral qualities!

Thus far, no such technic has been successfully developed. The opportunities afforded to those engaged in the administration of our medical schools and hospitals give your profession a much wider opportunity for personality study than is afforded to the faculties of our law schools in the appraisal of the ethical qualities of their students. In law schools, particularly in the "part time schools" from which the bulk of our candidates are derived, there is practically no opportunity for the teachers to gain more than a faint impression of even the physical and intellectual personalities of the students who attend the lectures and quizzes. We in the law greatly need the cooperation of your profession, and both professions, I feel, should much more insistently call for aid from our brothers in the general educational world in the solution of this problem. One of the essential difficulties, of course, is that in a large proportion of the cases character formation is so incomplete at the ages of 21 to 25 that an accurate appraisal of the future moral development of the candidate is difficult.

The most interesting of the methods which are being employed is that which the state of Pennsylvania has been

experimenting with. There the process of study of the character and fitness of the individual who desires to become a lawyer begins at the time he enters the law school and continues throughout his course of studies. Each prospective candidate is required to fill out a questionnaire before he begins and is assigned to a practicing lawyer as his adviser. This practicing lawyer is charged with the responsibility of interviewing the candidate from time to time during his law school course and studying his personality, his background, his associations, and his habits of living and of thinking. It seems probable that something along these lines in both professions may well be thoroughly tried out in the endeavor to obtain a more accurate method of testing ethical qualities.

This question of the extent of the existence of an ascertainable moral quality in a youth in his twenties, which quality is not at all accurately appraisable, is one which may well call for thorough psychologic study by members of your profession and by those interested in education.

There is one other subject to which I wish to refer. That is the subject of establishing certified lists of members of the medical profession qualified in the several specialties. The result of the decision of our New York Court of Appeals in the case of *Szold v. Outlet Embroidery Supply Co., Inc.* 274 N. Y. 271, opens up a field for advanced professional licensure which many thought was incapable of establishment as a governmental regulation. If, by such accrediting bodies as are therein recognized, it may be possible hereafter to create a limited group of qualified specialists and confine the giving of expert testimony in court to those who establish that they have been thus licensed and accredited, one of the great scandals in which both of our professions are concerned, namely, the use of incompetent and unqualified doctors who pretend to be specialists, may be largely if not entirely ended.

The School of Medicine in the University

ALPHONSE M. SCHWITALLA, S. J., St. Louis. The significance of the professional school's integration in the university is that all the constituent elements of a professional school can have a deeper and wider background than they could possibly have if the professional school were an isolated and self-contained unit. The research function, the teaching function and the welfare function of the professional school, for example, the medical school, thus become chapters in a larger book. Research in any one of the branches of medicine should borrow increased efficacy from the fundamental sciences which are fostered by the university as a whole. The teaching function should derive from the departments of education, psychology, sociology and social work a profounder grasp of the functioning of the human mind. The dynamic function of the medical school should derive meaning from the university's philosophy, economics and public relationships. Similarly too the structural and functional elements of the medical school will derive a profounder meaning when viewed from the standpoint of and when reciprocally they contribute to the corresponding structural and functional elements of the university as a whole. The curriculum of the school of medicine should be enriched in scope by reason of the readily available knowledge in other mental disciplines. The educational methods should experience a periodic rejuvenescence, administration should be liberalized, all of the progressive thinking in practically all fields of human knowledge and experience should more promptly and effectively be placed at the disposal of the medical school for immediate absorption and assimilation. No development in the field of general education should fail in achieving an immediate influence in the school of medicine. Each trend in education which has met the test of approved experience in any particular field should not fail to leave its imprint on a modified trend in a school of medicine. There are valuable trends in our universities which have not as yet found their fullest acceptance in our professional schools. I am thinking, for example of the splendid efforts made by our colleges of arts and sciences in the study of the individual student. The trends toward more careful selection, the study of specific traits as preparations for particular activities, the enlargement and broader concepts of personnel work, the carefully worked out principles in teacher selection, the application of well established procedures in teaching methods, the har-

monization of school curriculums with school objectives—in all these, certain divisions of the universities, in some of them the schools of engineering, in others the schools of law, in others the schools of business administration, and in others the colleges of arts and sciences have outrun if not the schools of medicine as a group then certainly some schools of medicine located in the very universities in which the most profitable work has been done toward the development of new techniques or new procedures, the establishment of new educational methods. Of course, I must insist that in some of our universities the school of medicine is actually in the front rank of the institution's development and is setting the pace not only for the other professional schools but also for the college of liberal arts and the graduate school. But this fact only emphasizes the need of a greater unification in the institution. I am pleading for a recognition by the medical school itself of the objective which it has to prepare physicians who will be equally prepared to practice not only in the spirit of the science but also in the spirit of the art of medicine, to prepare practitioners who will see the deeper meanings for human betterment of the work which they are preparing to do, who will be cultured gentlemen no less than keen diagnosticians, patient but forceful leaders in their communities no less than merely men who earn their livelihood by restoring the sick to health.

With reference to intra-university relationships, the school of medicine must depend on the liberal arts college to a great extent for student selection. Merely to demand a two or three years of college or even a bachelor's degree has in itself relatively little significance for the selection of a student as a student of medicine. Even the emphasis which has recently been thrown on the necessity of eliminating the so called pre-medical curriculum, extremely valuable though that emphasis is and the reciprocal emphasis on the necessity of broad culture as a necessity for medicine, still misses something of the deeper inwardness of the problem. The problem is still the detection of the particular student who should be encouraged to ambition the life and the responsibilities of the medical practitioner. Every school of medicine has much to learn from and much to give to the college of liberal arts in its own university. In these fields of educational endeavor, one would welcome the closest possible communication between the faculties of medicine and the colleges, between the administrators of both institutions, between faculty committees which have related functions in their separate institutions. One would welcome equally increased efforts at promoting these relationships on the part of the higher officials of the university who are responsible for the programs of the institutions as a whole, the presidents and the members of our various university boards and committees whose interests embrace both the professional and the professional units of their respective institutions.

In view of the rapidly enlarging program in graduate medical education, the school of medicine will find itself leaning more heavily on the graduate schools of our universities. The utmost caution is here indicated. On the one hand, the graduate school if it is to serve a real function as a promotional agency, can never forget that graduate medical education has not foresworn the objectives of all medical education and that graduate medical education must contemplate the more complete development of the practitioner in a specialized field of medicine. On the other hand the school of medicine must not and cannot forget that the future development of the specialist depends largely not only on the perfection of medical skills but also on a deepening of medical science. The efforts, therefore of the graduate schools and of the schools of medicine must be mutually cooperative if the end result is not to be lost sight of and if medicine, and all which better medical practice means, is to achieve the function for which it has been organized. Contradictory symptoms with reference to a weakening of the desirable relationships are developing in diverse places. On the one hand we find a progressive formalizing of programs in curriculums for graduate medical education, on the other hand we find a disregard of the art of medicine on the graduate school level and unjustifiable aggrandizement on the part of medical science. On the one hand again we find didactic methods in graduate medical education which would no longer today be tolerated in the more progressive undergraduate schools of medicine and on the other

hand, we find programs which leave the graduate student of a medical specialty so much to his own devices that his efforts at self education are the only efforts which are made and to which the institution contributes little more than the fact that the student has been registered. These contradictions are so serious because in many institutions we are just now passing through the period of origins.

No one can be sure that the graduate medical education of the future will have the same objectives as undergraduate medical education, but at least as a starting point our aim at the present moment, our aim at graduate medical education at least in the clinical sciences and arts is to achieve in a better and more specialized manner what we have previously achieved in a general way through our undergraduate medical curriculum.

Medical education can never be unmindful of the enormous debt of gratitude which it owes to the universities. The universities have been most generous in their support of this particular professional school, mindful of the great purposes which medical education attempts to subserve. A school of medicine cannot support itself on income from students alone. The school of medicine, therefore, must in most institutions depend on the university to supplement the income derived from student fees. Different universities again support their schools of medicine with variable percentages of the total costs of the school of medicine. The financial support which the university gives to the school of medicine is an expression of the university's altruistic attitude toward its clientele, toward its student body and toward the communities which the university serve.

Factual data can be supplied to show that university influence in the school of medicine is not without its dangers. We have been accustomed to thinking of certain departments in the school of medicine, such as the department of biochemistry or of anatomy or of physiology or of bacteriology, even of the clinical departments, for example, pediatrics, internal medicine or surgery, as university departments. If the meaning of the phrase is simply this, that these departments are conceived as divisions of the university in the same sense as are the departments of Latin or of sociology or of physics, the implications may be innocent enough. If, on the other hand, the implication of a university department is that, in these various departments, students of all kinds may assemble and that student body in courses conducted by these departments may be made up of students from diverse professional groups as well as of students from the graduate school or liberal arts college, then there may be and sometimes there is considerable danger in this form of organization to the student of the school of medicine. Into a class composed of students with specific objectives and conducted by such teaching methods as I have suggested, we sometimes introduce students from other divisions of the university, from other professional schools or sometimes students of the liberal arts. I will not deny the possibility that other than medical students can profit by such administrative procedures, but my concern is largely for the diffusion of professional interest which arises from the presence in a class of a large number of other than medical students. Other examples might be chosen to illustrate the point. One might conceivably permit students of medical social service, for example, in a course on psychiatry as given to sophomores or juniors on the assumption that the medical social service student has already achieved to some extent at least an understanding of the medical point of view through a thorough course in medical essentials and especially through exposure to field work in a hospital or in an outpatient department. But to admit into a class in psychiatry as taught to medical students a group of students from the family welfare field or the child welfare field whose whole approach to a medical problem has been that of a person who regards the health problem as incidental, to allow such students to follow the technical discussions of a complicated case history seems to me to be not only an unwarranted but also an educational indefensible procedure. I am not pleading for the erection of Chinese walls around the departments of our schools of medicine. Nevertheless, in order to place better medicine at the disposal of the nation it seems essential to safeguard the processes of medical education. By all means let us extend the meaning of medical education to other groups than simply our medical students, but when we are instructing medical students and thus prepar-

ing the practitioner of medicine we can scarcely at the same time and by the same methods expect to prepare what I cannot but regard as the lay mind for the understanding of hygiene and health problems. One is an effort in professional education, the other is an effort in popular education, adult education, even though it is followed under the auspices of a graduate school.

The Functions of the Special Examining Boards

DR WILLARD C. RAPPEYE, New York. The recent advances in the graduate fields would not have been possible except for the phenomenal elevation of medical education in the United States since 1900 through the efforts of the Council on Medical Education and Hospitals, the foundations, the universities, the licensing bodies and private philanthropy. Graduate training has always been a well recognized part of the educational programs of leading medical schools and teaching hospitals. Present plans for the extensive development of such training to meet the need for better rather than more physicians are based largely on the long experience of teaching institutions.

In response to the desire to establish common aims within single specialties, the American Board of Ophthalmology was created in 1916 and the American Board of Otolaryngology in 1924. Other boards were organized and shortly each specialty sought a board of its own. These several developments laid the groundwork for the organization of the Advisory Board for Medical Specialties in 1933. This body was founded by representatives of the different groups of specialists and of the medical schools, hospitals and licensing bodies to coordinate the efforts of the individual boards in securing reasonable uniformity in standards and functions. The action of the House of Delegates of the American Medical Association in the same year arose from recognition of the desirability of central approval of the requirements for training in the clinical specialties.

The programs are moving forward in response to the need in every area of the country of a proper number of specialists who, in addition to a sound basic preparation, are qualified by graduate training, technical skill, judgment and experience to perform the specialized services which some patients require. It is obvious that opportunities for advanced training must be made available because the usual medical course and internship aim to provide a student only with the elementary and introductory principles of medicine. The mass of scientific knowledge and the variety of skills needed in all divisions of practice are far too extensive to be covered satisfactorily in the usual course. No phase of medical service is more important than the further training of all physicians and particularly the identification of those who wish to limit their practice to a specialty.

The primary function of each specialty board is that of promoting adequate training in its own field of practice. In the certification of specialists, each board recognizes the necessity of adapting accepted standards to meet the situation of those doctors already in practice who are partially trained in a special field and also that group of older physicians who are well recognized in their specialty. The latter constitutes the founder groups in the different fields and the former will gradually disappear as the younger graduates complete the more formal type of training which is recognized by the specialty boards as the most desirable. Other considerations include the conversion of many existing facilities into acceptable residencies. Such residencies should provide satisfactory laboratory instruction and the development of a teaching personnel in many hospitals not now engaged in an educational program. Financial aid for such projects will have to be found.

Considerable wisdom and patience must be exercised in reconciling those phases of graduate medicine which are related to the limitation of practice to a single field and those which concern the training and other qualifications of an individual to meet his responsibilities in any given specialty. Fortunately, there is wide recognition of the dangers of setting up watertight, more or less artificial compartments of practice and training. Specialized practice concerns itself with the patient as an entity quite as much as with the particular disease with which one of his organs may at the moment be involved. In discharging their functions, the boards are trying to avoid rigid rules and regulations which would even attempt to stand-

ardize practice in the different fields. They recognize that the program of graduate medicine is one of education broadly conceived and that their requirements must be kept flexible.

The unit of true education is the student, who should be given every opportunity for the development of initiative, self reliance, resourcefulness, and proper habits as well as methods of study. The plans for graduate medicine and for recognizing properly qualified specialists must be closely articulated with parallel educational programs for the general or family physician, who must provide the basic professional services in every community.

The boards must of necessity have close working relationships with hospitals, in which most of the graduate preparation must be provided. A function of the boards is to make clear to hospitals and the profession that the internship should be looked on as a part of the basic training of a student and that it should not be regarded as advanced equipment for the practice of a specialty. The boards must function in close relationship to the licensing bodies in the different states. There is abundant evidence that the functions of the boards of specialists are only a part of the larger plan of medical education. It is highly important that these functions be harmonized with the developments and needs of the other parts of the educational scheme. The premedical student, the medical student, the intern, the resident, the general practitioner, the specialist, the teacher, the investigator and the public health administrator should be regarded from an educational point of view merely as different phases of the training of personnel to meet the health needs of the country. The problems from college preparation to retirement from professional life should be looked on broadly as parts of a single educational program. Some of these parts are primarily within the jurisdiction of universities, some are largely within the domain of the hospitals, others are in the various fields of practice, and some are under direct governmental regulations.

There is urgent need for coordination of the various subdivisions of medical education and for better definition of the several areas of responsibility of national and state agencies, universities, hospitals and professional bodies dealing with portions of the whole program, if medicine in this country is to meet fully its obligations.

DISCUSSION

DR. WALTER L. BIERRING, Des Moines, Iowa. I wish to relate my remarks to the paper of Dr. Rappleye, who has brought out the relation between the training of the specialist and graduate education. There is no doubt that the time which will be required for this specialized training will vary and will be determined more in the years to come. There is a feeling that specialized practice should not be entered until at least ten years has transpired from the time of graduation or the completion of a hospital intern year. Special training belongs in the field of graduate education, but it is hoped that in standardizing or in outlining a course of study it may not be strictly confined to a certain quota of hours or specific curriculum, but that there may be even more elective privileges than are now being developed in undergraduate curriculums. It has been the experience of one of the examining boards or the method that has been devised by them, that of internal medicine, of not in any way particularly indicating the institution or the course of study but depending largely on the individual himself, placing the responsibility of the training on the individual concerned, whether it is in this country or in a foreign country, in a small or a large institution, that is his responsibility. The determination of the qualifications of the individual for the specialty he wishes to practice lies entirely with the particular certifying board. It is the responsibility of the board to determine whether that training is adequate for his being certified in that specialty.

DR. BURT R. SHURL, Detroit. With an experience of fourteen years on a special examining board during which we have examined more than 2,500 men and the number of failures has been some 20 per cent, and is one particularly interested in originating the Advisory Board for Medical Specialties, it seems to me it is time to lay out a definite program that will have to it a vision and a far-reaching plan throughout this country to furnish sufficient opportunity in graduate training

for these various specialties. I have felt through these years that the pendulum has been swinging so rapidly in medicine that we err many times in our enthusiasm by being carried away into a field that becomes much too limited. The spirit of liberalism in education must come back, so that we recognize the true value of basic general surgery and general internal medicine. While we have these numerous societies and numerous boards and numerous governmental controls, it seems to me that some of those should be eliminated. In Wayne University we have developed a course for all interns in all hospitals of the city of Detroit, where they may have a splendid course in anatomy and pathology, which we find are the two weak subjects as these men come up before us for examination. While we have in otolaryngology only 150 vacancies throughout the year, there are still inadequate training grounds for those men, and that certainly must be developed in each of these special boards.

(To be continued)

Book Notices

Pathology of the Central Nervous System A Study Based upon a Survey of Lesions Found in a Series of Fifteen Thousand Autopsies By Cyril B Courville MD Professor of Neurology and Psychiatry College of Medical Evangelists Los Angeles Cloth Price \$5 75 Pp 344 with 200 illustrations Mountain View California Pacific Press Publishing Association 1937

The present volume is an excellent work devoted mainly to the gross pathology of the brain and the nervous system The author has studied fifteen thousand brains and spinal cords post mortem, twelve thousand of which came under his personal observation From this vast amount of material he has organized a textbook which covers thoroughly the innumerable descriptive phases of his cases The work follows, in general, classifications set up clinically Part one is devoted to congenital anomalies and malformations, part two to diseases of the intracranial blood vessels, part three to infectious diseases of the central nervous system, part four to the effects of trauma, part five to intoxications, part six to diseases of unknown etiology and part seven to tumors of the intracranial and intraspinal spaces Little case history material is given on individual cases and the microscopic details are largely left for some one else's discussion, but each one of the major pathologic conditions found in the brain and spinal cord—the former in particular—is covered in some detail, particularly in relation to the gross appearance and the circumstances of causation In spite of the vast amount of case material studied, statistical information about anomalies, peculiar variations, numbers of cases of rare entities and other rather obscure phases are not treated very thoroughly, but nevertheless the material in the book does not seem to be duplicated elsewhere in the specific form in which it appears here For each condition one finds one or more excellent photographic reproductions showing the exact appearance of the organ and, in some cases, showing the gross tissue changes A number of beautifully executed drawings illustrate the clinical point under discussion and anatomic features in connection with the pathologic entities, but the text does not devote itself very much to clinical observations, physiology or obscure disorders Special attention must be drawn to the appendix, in which the author lists a number of clinicopathologic aphorisms which seem to be, on the whole, true and are rather pithily presented Many of them direct the student's attention to obscure pathologic conditions that might be neglected Others offer general rules which might well be remembered in all cases dealing with disorders of the nervous system This book is well written, has been carefully edited, and would satisfy a need for both the neuropathologist and the clinical neurologist who desires something between the general clinical neurologic textbook and the usual microneuropathologic work

La vie médicale aux XVI^e XVII^e et XVIII^e siècles Par le Docteur Paul Delaunay membre de la Société française d'histoire de la médecine Paper Price 40 francs Pp 556 with 114 illustrations Paris Le François 1935

Professor Delaunay's *Vie médicale* is a splendid addition to this series in the historical field It is limited in its scope to French medicine and excludes surgery because of the medieval schism between medicine and surgery, which continued in France, though not in Italy, when the physician became a medicus The work treats of the life of the medical student and of the private, professional, corporative, religious, political, social, intellectual and doctrinal life of the full fledged and active *medecin* The text is amply documented with citations of authorities and finely illustrated with well selected reproductions from contemporary prints, portraits, engravings and paintings It thus affords a detailed and accurate picture of the preparation and professional activities of the physician in France and his wide cultural relations from the opening of the sixteenth century up to the close of the eighteenth The Faculty of Medicine was established at Montpellier in 1220 A D, giving stability, continuity, wider influence and permanent privileges to medical education A federation of teachers under the egis of the chancellor of Notre Dame opened formal instruction in Paris Chairs of medicine multiplied as the universities were organized in the thirteenth to the sixteenth centuries until

students had a wide field from which to choose. It was the custom for medical students to migrate from school to school even across national boundaries. Vesalius began his studies in Belgium, went to Montpellier and to Paris, reentered Louvain, took his bonnet at Basle, and taught at Padua. This academic dromomania had its origin in the international character of learning, the inequalities in instruction, the transfers of teachers and the wanderlust of youth. Religious turmoil accompanying the Reformation scattered pupils and teachers, and the epidemics of plague repeatedly decimated and scattered both students and faculties. At Montpellier in 1527 the students were taxed at the "anatomy" for gratuities to the watchman who brought the body, to his wife who furnished the linen, to porters, washers, interpreter, prosector, beadle and janitress and her children who ran errands, to say nothing of charges for wine, for washing, vessels for viscera, incense, fuel and candles. Library facilities were meager. In 1527 Montpellier had fifty volumes. Books were chained to keep them and fees were charged for their use. Catalogues emerged to prevent losses. Herborizations took students afield and tickets admitted them to botanic gardens of medicinal herbs. The family life of the physician, his office, furniture, library, costume, bedside manners, remuneration, professional ethics, relations with apothecaries, patients, the nobility and the court are all passed in review. The author reviews the contributions of the profession to the intellectual life of these three centuries, tracing the decline of humanism, their contributions to anatomy, physiology, botany, zoology, physics and agriculture, their share in the formation of academies and learned societies, and their aid in forwarding scientific publication and establishing high standards of scientific work. He traces the changes in medical doctrine from wreckage of the galeonic school to the organized knowledge of the encyclopedists. This scholarly treatise is an epitome of the history of medicine in the formative centuries during which the arts and science of medicine emerged from scholasticism, superstition and charlatanism into the clearer light of the dawning modern period.

Operative Obstetrics. A Guide to the Difficulties and Complications of Obstetric Practice. By J. M. Munro Kerr LL.D. M.D. F.R.C.O.G. Obstetric Surgeon Glasgow, Maternity Hospital Glasgow. Fourth edition. With the assistance of Donald McIntyre M.D. F.R.C.O.G. Consulting Obstetric Surgeon Barshaw Maternity Hospital Glasgow and D. Fyfe Anderson M.D. Senior Assistant to Professor of Obstetrics and Gynecology (Vulvar Chair) Glasgow University. Cloth. Price \$12. Pp. 647 with 338 illustrations. Baltimore: William Wood & Company, 1937.

The fourth edition of this noted work, previously entitled "Operative Midwifery," has been brought down to date by thorough revision and rewriting. In this task Dr. Kerr acknowledges the assistance rendered by Donald McIntyre and D. Fyfe Anderson, who have collaborated with him in this new edition. The book is unique in that it deals only with those phases of obstetric practice which require operative intervention. Other abnormalities, such as toxemias of pregnancy and, logically, the normal aspects of obstetrics, are completely omitted. Kerr calls attention to the fact that in England, as in America, maternal and fetal mortality and morbidity are unnecessarily high, emphasizing that the knowledge of when and how to intervene is of paramount importance. His opening paragraph is an essay in itself.

Nature in parturition, although generally following a certain course, refuses to be trammelled by hard and fast rules. It is important for the accoucheur to remember this and to appreciate within what limits Nature may be allowed a free hand. The mistake is too often made of forcing getting this and of interfering when with a little patience, it would have been unnecessary. But if it is of importance that the accoucheur should appreciate the natural variations of parturition, it is equally important that he should recognize when nature is at fault and that he should do this as early as possible. *He must not presume that a parturition is normal. He must not be content until he has satisfied himself that it is not abnormal.* Again and again one sees how failure in this respect results in complications being overlooked until they cannot be remedied and the child's and even occasionally the mother's life sacrificed or greatly endangered. This does not imply that he must always interfere early in labour in many cases of dystocia. *Timing of interference is the all important detail.*

In general there is little but still some difference between obstetric practice in this country and that advocated by Kerr. He discusses the importance of antepartum care even though it has not yet succeeded in materially lowering the death rate, saying it has not had a "fair deal." He speaks of a complete

examination in the thirty-fourth to thirty-sixth week to discover abnormalities and to anticipate dystocia. By this he does not mean to indicate that no earlier routine care is necessary though he fails to specify this. From his writings and those of other English obstetricians it often seems to appear that the pregnant women in England have not been generally taught to prevent themselves for antepartum care as early in pregnancy as do the women in this country.

American obstetricians will probably disagree with Kerr's advocacy of amniography, or the injection of an opaque medium through the abdominal and uterine walls into the uterine cavity for the purpose of x-ray visualization. This is proposed by him for diagnosis of placenta praevia in doubtful instances. He finds it necessary still to argue for the use of rubber gloves, he urges more general masking of attendants on patients in labor and during the early puerperium he favors the use of vaginal antiseptics during labor, unlike many British obstetricians, he prefers the dorsal position for delivery. Kerr utilizes the lateral type of episiotomy on occasion but considers episiotomy "seldom necessary." These various points of view, with others, are cited because they cannot fail to be of interest to those of us on this continent who will wish to compare our procedures with his.

He favors traction on the umbilical cord for delivery of the retained but detached placenta, making certain, however, by placing a marker on the cord at the vulva that the placenta has first become detached. This marker must have advanced before he permits traction, but when advancement has occurred he favors this in preference to any considerable amount of pressure over the fundus. He does not approve of attempts at manual or instrumental rotation in occipitoposterior presentations. While he still advocates the use of pubiotomy (hebotomy) under certain circumstances, he fails to recommend it in impacted face presentation with the chin posterior, stating that in this situation there "is no option but craniotomy even if the child be living." He favors forceps delivery of the after-coming head in breech deliveries, he cautions wisely against the dangers of Kristeller expression during ordinary deliveries.

The chapter on contracted pelvis is excellent, the old dimensional classification being retained but with generous reference to the work of Caldwell and Moloy, Thoms, and Jarcho. He appreciates the value of the x-rays in the diagnosis of contracted pelvis but, like the experienced obstetrician that he is, states that trial of labor is more important in borderline cases. The various roentgenograms in the book are splendidly clear, but the other illustrations are for the most part simple line drawings, not at all comparable to the excellence of the text. The book is not firmly or securely bound but the paper and printing are of fine quality. This volume should be especially helpful to the obstetric specialist and of great value to the practitioner doing obstetric work.

Innere Sekretion und Chirurgie. Von Hans Hanke Dr. med. habil. Dozent für Chirurgie an der Universität Freiburg im Breisgau. Paper. Price 24 marks. Pp. 326 with 18 illustrations. Berlin: Julius Springer, 1937.

The study of internal secretions appears to hold out as great a promise for medicine as did bacteriology sixty years ago. The acquisitions to medical knowledge which have come through investigation of the glands of internal secretion have been numerous. It may seem a bit odd that a surgeon would essay to encompass this somewhat strange field in a monograph. Yet as the author points out the surgeon was among the first of medical practitioners to concern himself over endocrinology. Through the first unhappy experiences of surgeons with the removal of goiters, much was learned concerning the behavior of the thyroid and parathyroid glands. The continued activity of surgeons in the romantic field of the endocrines has augmented medical knowledge with relation to the pituitary, the parathyroid, the pancreas and the adrenal glands. In this sound and substantial monograph the author has collected much useful information. The subject matter treated consists of the thyroid, the parathyroids, the thymus, the insular apparatus of the pancreas, the adrenal, the hypophysis, the pineal body and the sex glands. The important features of minute anatomy of the various glands are related. Then follows generally a complete discussion of the accepted and debatable physiologic functions

together with mention of the relation of the gland under discussion to other glands of internal secretion. A discussion of diseases affecting the gland and the role of surgery in treatment completes each chapter. A few more well selected illustrations would have added much to the text. The author shares apparently the attitude, heard more commonly in Europe than on the American continent, that the presence of a goiter sensitizes a patient to iodine. American students of the goiter problem will no doubt attribute this reaction in part to a prejudice which still survives from the so called Jod-Basedow (iodine hyperthyroidism) described by Kocher in 1910. It seems somewhat strange to learn (p. 206) that only two patients with hyperinsulinism had been operated on successfully in Germany up to the publication of this monograph. The author, though recognizing the relationship of the hypophysis to the normal descent of the testis, is not nearly as enthusiastic over the accomplishment of antuitrin-S in the treatment of failure of testicular descent as are many American writers. Much encouragement for the success of hypophysis transplants is offered in the reports of Sauerbruch and Kryn (p. 277), who observed startling improvement in Simmonds' disease (hypophysial cachexia) following implantation of hypophysial tissue from the calf. The results of other glandular transplantation, whether heterografts or homografts, are not good, as is admitted by the author. This splendid monograph deserves to be read and studied widely. There is much to commend and little to criticize in the volume. It can be enthusiastically recommended not only to surgeons but to any one who seeks authoritative information on the physiologic mechanisms of the glands of internal secretion.

Mental Therapy Studies in Fifty Cases. By Louis S. London, M.D., Medical Officer, United States Veterans Bureau. Volumes I and II. Cloth. Price \$12.50 per set. Pp. 427, 428, 774 with 22 illustrations. New York: Coriel Friede, 1937.

This is a rather extensive psychoanalytic work consisting of analyses of fifty individual cases, the majority of which were treated by the author and all of which were studied in his practice. The author scarcely can be considered an orthodox psychoanalyst. While many of his explanations fall definitely under the Freudianegis, he does not use, as a general rule, the technique of Freudian psychoanalysis. Instead, he uses the method developed by Stekel, which consists of a greater use of interpretation of and explaining to the subject the basis of his mechanisms rather than allowing him to come on it of his own accord by the use of uncontrolled association. While the basic theories behind the two types of psychoanalysis are almost identical, the explanation of the mechanism in some of London's cases would probably not elicit a hearty corroboration from the orthodox analyst. Nevertheless, there is in this volume much material that is interesting. Each case is presented in some detail, although not as completely as one usually finds in a study of psychoanalytic material. Each case, too, is designed to represent the particular type of deviation, such as a cardiac neurosis, a gastric neurosis, an anxiety neurosis, sexual impotence, sadism, masochism, schizophrenia or manic-depressive psychosis of various types. The author's descriptions of the psychotic behavior and the everyday life of the neurotic individual are meager. Much stress is laid on the symptomatic difficulties and the chief complaint. A history is given in each case showing the background, the medical observations, relationship to the parents, early sexual history and some dream material which would tend to explain the dynamism involved in the particular deviation. Each case is concluded with a comment which is rather too terse to be completely significant. The cases unfortunately are not clear cut. The psychiatrist who wishes to enlarge his horizon and to understand the dynamics of behavior to a greater extent will be sadly disappointed in the present work. While certain dynamisms are mentioned by name, and dreams may be interpreted to point out the associational machinery involved and possibly the complex material lying behind them, one cannot see the logical connections between the material and its evaluation. This is particularly true in the volume which deals with the psychoses. One is not convinced that the patients were suffering from a psychosis in the first place, and in those cases in which there seems to have been a favorable result from the author's treatment the manner in which it was brought about is not at all clear. As a matter of fact, although the

author implies and of course the title indicates that the book is to be devoted to the therapeutic aspects of the cases, the only treatment apparent from the way these cases are written up is the fact that an analysis was undertaken, the dreams were analyzed, and the patient was given some insight into his mechanisms. How these were carried out is not described. There should be a detailed explanation of what techniques were used, at what time, what particular features were stressed, how exactly insight was brought to the patient, and what the results of the various stages of treatment proved themselves to be as the case proceeded under the author's care. There is a great deal of dogma and little explanation. As a gesture to indicate that treatment is necessary in psychiatry and as a suggestion that conditions of widely diverse nature might be subjected to various kinds of treatment, the book has value. As a guide to treatment for the use of psychologist, neurologist, psychiatrist, and the general practitioner, who will find the cases presented of decided value in their practice, its importance is doubtful.

Emotional Hygiene: The Art of Understanding. By Camilla M. Anderson, A.B., M.D., Assistant Professor of Nursing Education, Duquesne University, Pittsburgh. Cloth. Price \$2. Pp. 242 with illustrations by Dorothy G. Stevenson. New York & London: J. B. Lippincott Company, 1937.

The rather popular presentation of this book with its subtitle "The Art of Understanding" makes one suspect that this is another one of those superficial works devoted to telling a patient how to cure himself without a doctor or how to adjust all the problems in his life. On reading it, however, one immediately notes that the language is extremely easy to comprehend and it proves to be a small but substantial volume full of excellent factual material which well deserves perusal. It consists of three parts. The first one is devoted to a rather general and perhaps superficial presentation of mental mechanisms, with a simple explanation of behavior and a description of personality types, emotional patterns, escape mechanisms and similar features in the biologic and other bases of the behavior pattern. This part is short and rather generalized but accurate. The second part is devoted to specific discussions of how to meet problems arising from personal problems, in dealing with patients, relatives, colleagues and the environment in general. The third part is a discussion of various phases of nursing, leading one to believe that the book is primarily intended for nurses, since the author is an instructor in nursing education. The introduction does not make this clear, although the style is pointed definitely in the feminine reader group. There are many chuckles and pertinent illustrations, both verbal and pictorial, and practical cases are taken up and discussed in an intelligent manner. This is one of the few books on mental hygiene sufficiently well written and widely enough applicable so that it might be given to the interested reader without medical training who requests a book on this subject.

Radiation Therapy: Its Use in the Treatment of Benign and Malignant Conditions. By Ira I. Kaplan, B.Sc., M.D., Clinical Professor of Surgery, New York University Medical College. Cloth. Price \$10. Pp. 558 with 198 illustrations. New York: Oxford University Press, 1937.

The volume opens with a short survey of the historical development of radiation therapy, including radium and x-rays, the physics of x-rays and radium, descriptions of types of apparatus for the production of x-rays and their measurement, and the use of electric currents as a substitute for scalpel surgery in cutting and coagulating tissues. There then follows a chapter on irradiation in dermatology which includes the treatment of infectious diseases of the skin and of superficial neoplasms. The remainder of the volume deals with the irradiation of tumors, the classification being based on a regional arrangement, the tumors in each organ or tissue being taken up separately. Extensive bibliographies are attached to each chapter and the different types of tumors in different situations are copiously illustrated with photographic reproductions of the patients and photomicrographs of the tumors.

The volume contains an immense amount of useful information in compact form, but in the effort to cover the vast field a dogmatic type of presentation has been assumed which would lead the reader to think that radiation therapy has a far greater value than it really possesses and that it can be put on a prescription basis. There is a great deal of repetition in which

it is definitely stated that the radiation should be given at such and such a voltage with such and such filtration, which might lead the uninitiated to believe that all that is necessary is to apply this radiation in order to get good results. There is already too much of this routine application of x-rays to a vast number of conditions in which little or no benefit is actually obtained by such irradiation and therefore the book is dangerous for the beginner, who may be led to think that he can obtain results which the expert knows are rarely seen. It would have been much wiser had the volume covered less ground and the limited fields in which radium and x-rays are effective considered in greater detail.

There are also evidences on almost every page of haste in preparation, and numerous misspellings have been found, with misprints and the use of incorrect expressions. As an illustration of the latter, it may be a comfort to know that "females are rarely involved with lip cancer," and the phrase might well have been omitted as not illuminating the subject of cancer of the lip to any extent. An example of excessive optimism is the statement that nausea or vomiting occurring after x-ray treatments can be controlled by citric acid fruit juices or small doses of sodium bicarbonate. The author knows perfectly well, for he mentions the fact in another place, that in a certain proportion of cases nothing controls the nausea or vomiting and that treatment may have to be abandoned because of this fact. Speaking of melanomas, the author says that when metastatic lesions of the lung are present the whole chest is treated with high voltage x-rays, daily doses of 150 roentgens being given to each area alternately until a total of from 1,500 to 2,000 roentgens has been given to each area. The beginner may assume from such a statement that such irradiation is of benefit, but unfortunately the reverse is true. Speaking of mixed tumors of the salivary glands the statement is made that they do not metastasize, that the "gland" must be completely excised and that as soon as the wound is healed radiation should be administered. There are some who think that, since these tumors frequently recur locally, the tissues should not be damaged by radiation of 2,000 roentgens as recommended but should be reserved for further surgical treatment, which is often effective.

Perhaps these criticisms seem unimportant, but there is no satisfactory modern book on the subject of radiation therapy, and it is to be hoped that a prompt and thorough revision of this text along the lines indicated will be made so that the author's wide experience and judgment may be available to the large number of radiotherapists who are attempting with insufficient experience to treat patients with malignant disease for whom radiation is the only hope.

Porphyria und Porphyrikrankheiten. Von Priv. Doz. Dr. A. Vannotti, Sekundärarzt der Medizin, Universitätsklinik Bern. Paper. Price 27 marks. Pp. 286 with 64 illustrations. Berlin: Julius Springer, 1937.

It is probable that the total occurrence of cases of true porphyria congenita in Europe and the United States since Gunther's paper in 1911 is less than the number of papers that have been written on the subject. In the last decade however, it has been gradually recognized that the porphyrias are of more significance to medicine than association with some pathologic curiosities. Porphyrins are fundamental components of the hemoglobins and at least some of the oxidation catalysts (cytochrome C) as well as of the chlorophylls. The brilliant chemical studies of Hans Fischer and the spectroscopic work of Dhérain have not escaped the attention of clinical investigators, especially in Germany, who are studying porphyrin metabolism in a wide variety of conditions. Reviews on the clinical significance of the porphyrias have been published recently by I. T. Brugsch (*Ergebn. d. ges. Med.* 20: 423, 1935; *Ergebn. d. inn. Med. u. Kinderh.* 51: 86, 1936). The present book by Vannotti covers clinical questions in detail in addition to voluminous literature on spectroscopy of the porphyrias, the results of experimental administration of porphyrias to both animals and man, the relation between porphyrias and iron metabolism and general studies on porphyrias in plants, animals and bacterial cultures. The chief criticism of Vannotti's book is on the score of omission. One could wish for a more thorough treatment of the chemistry of the several porphyrias, as this is fundamental to an understanding of the clinical ques-

tions. The omission of a detailed discussion of the "H₂ number" and differential solubilities of the porphyrias will be regretted by investigators who are concerned with separation and quantitative estimation of the various porphyrias in biologic materials. The nine page section on methods for estimation of the porphyrias is only a brief introduction to these complicated questions. Vannotti repeats the familiar dictum about the role of porphyrias in photosensitization, but it should be mentioned that recent studies by Blum and Pace (*Brit. J. Dermat. & Syph.* 49: 465 [Nov.] 1937) fail to confirm any general relation of porphyrias to hydroa and similar lesions resulting from light sensitivity. Studies on patients at the Mayo Clinic in 1936-1937 by Brugsch, Keys and Brunsting yielded the result that light sensitivity did not occur in any of the observed cases of moderate porphyria and that in none of the observed cases of light sensitivity was there any appreciable disturbance in porphyrin metabolism. Vannotti's book is well organized and shows, in the discussions, the understanding that comes only from having personal experience in a field of study for some years. The book should be useful to all who are interested in pigments and their metabolism, it will be indispensable to students of the porphyrias. It is unfortunate that there is as yet no work in English of comparable scope.

The Management of the Pneumonias for Physicians and Medical Students. By Jesse G. M. Bullowa, B.A., M.D., Clinical Professor of Medicine, New York University College of Medicine, New York. Cloth. Price \$8.50. Pp. 508 with 142 illustrations. New York: Oxford University Press, 1937.

Dr. Bullowa's book includes almost all phases of pneumonia except pathology. He begins with classification of the pneumonias and then gives an account of the clinical picture, the laboratory, physical and x-ray examination and the various forms of treatment. The data which he presents are drawn largely from his own extensive clinical experience at the Harlem Hospital. The book is by no means evenly written. The best chapters, those on laboratory examination and serum therapy, are evidently subjects with which he is most competent to deal. Unfortunately the author feels called on to make comments now and then on immune processes in pneumonia, a subject with which he is evidently unfamiliar, as many of his statements are misleading and others have no foundation in known fact. For instance, he states that among the factors which control invasion of the blood stream by the pneumococcus are bacteriolytic in the serum and the pneumococidal action of the blood platelets. Evidence does not exist for either one of these two antipneumococcal activities of the blood. The chapter on oxygen therapy is much too detailed and theoretical for the clinician who wants to know the best method of giving oxygen, its indications and what can be expected from its use. Likewise, many of the charts are too complex. Even after considerable study one is not always sure of their significance. The bibliographies at the end of the chapters give the impression of being thrown together without any order and do not always include the most important contributions to the subject. In spite of its defects the book contains a great deal of valuable information and presents for the first time a collected account of the specific pneumonias caused by the different types of pneumococci I to XXIX. The author's observations on the results of the newly developed antipneumococcus rabbit serum are of particular value in view of the probable availability of this therapeutic agent in the near future.

The Family in Health and in Illness. By Florence Brown Sherbon, A.M., M.D., Professor of Child Development and Health of the Family Department of Home Economics, University of Kansas. Cloth. Price \$3.50. Pp. 516 with 200 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1937.

This book, prepared primarily for college students but with the purpose of continued usefulness after graduation is a household manual of health and disease, containing much useful reference material but with certain glaring defects. It attempts too much in some instances, with the result that its treatment of certain topics is inadequate, and it contains statements with which many physicians will disagree. For example the routine use of commercial mouth washes is said to be commended as a routine habit. By whom other than the manufacturers? Sulfanilamide gets a paragraph, this is either too much space

in such a book or too little, especially when it includes the following invitation to self medication "Sulfanilimide is effective when taken by mouth and does not produce marked physical reaction" Descriptions of the uses of procaine, ephedrine and epinephrine in one sentence as drugs which are used "to shrink the congested membranes and open up the breathing passages" are out of place in such a book, even when followed by the warning "Novocain and adrenalin should never be used except by a physician, and ephedrine should not be used continuously or in chronic conditions except under a physician's advice" If that is so, why should they be mentioned here at all, especially in terms which first seem to recommend, then condemn? The only result, as any physician should realize, will be to stimulate attempts at self medication, despite warnings against it appearing elsewhere in the book For the most part the book is serviceable, except that efforts to be brief often make the discussions, especially of the specific diseases, unsatisfactory, as for example this sentence from the description of pernicious anemia "Absence of gastric acid and spinal cord paralysis is usually noted in some degree and is almost a specific symptom" Aside from the faulty sentence construction, which might lead the inexperienced reader to infer that "absence of spinal cord paralysis is almost a specific symptom," whereas the reverse is meant, this information is of absolutely no use to the reader of such a manual, especially when this is almost all there is on symptomatology of this disease Moreover, false hope is held out for prevention of pernicious anemia in the statement that it "consists in pursuing a 'balanced' mode of life especially with reference to a diet containing a full amount of vitamins and minerals" Such questionable passages greatly impair the value of a book that contains much useful information How is the untrained reader going to separate the wheat from the chaff?

Illustrations of Regional Anatomy By E B Jamieson MD Senior Demonstrator and Lecturer Anatomy Department University Edinburgh
Section I Central Nervous System Section II Head and Neck Section III Abdomen Section IV Pelvis Section V Thorax Second edition Paper Loose leaf Price \$2 50 \$3 50 \$2 25 \$1 50 \$1 75 \$15 per set of 7 sections 48 plates 63 plates 37 plates 33 plates 30 plates Baltimore William Wood & Company 1937

Any work on the subject of anatomy is usually useful These handsome illustrations are no exception Bound in loose-leaf and printed on one side of the paper, they are evidently intended for the student as a guide for his notebook and his dissection The sections under review exclude the limbs but contain more than 200 plates on regional anatomy of the rest of the body The drawings are diagrammatic, many in color Usually they are replete with legend, at times seemingly cluttered No doubt these illustrations can aid in clarifying to the student many anatomic mazes, but the various large textbooks, of the size and quality of Gray's, are cheaper and perhaps still best for the medical student, old and young

Synopsis of Digestive Diseases By John L Kantor PhD MD Associate in Medicine Columbia University New York Fabrikoid Price \$3 50 Pp 302 with 40 illustrations St Louis C V Mosby Company 1937

This pocket size book presents a clear and concise though necessarily abbreviated, account of the field of gastro enterology The book is attractively printed, the style lucid and direct Statistical evidence is drawn from the author's large practice The discussion on treatment is in many cases inadequate However, classic symptomatology is well presented

Diseases of the Soft Structures of the Teeth and Their Treatment A Text book for Students and Practitioners By Hermann Prinz MD DDS MD Professor of Materia Medica and Therapeutics the Thomas W Evans Museum and Dental Institute School of Dentistry University of Pennsylvania Philadelphia Second edition Cloth Price \$6 50 Pp 500 with 308 illustrations Philadelphia Lea & Febiger 1937

This deals only with diseases of the pulp, gingivae and periodontal membrane and fits the teaching program in many dental schools This fact and the general excellence of the text account for the popularity of the first edition The section on pulp diseases and root canal treatment is unusually complete and authoritative, the part on pyorrhea is least satisfactory The brief historical reviews are unusually complete and enlightening The text is replete with formulas and prescrip-

tions where drug treatment is indicated The disease classifications are redundant and in places confusing, as are also disease names Dental students and dentists will find this to be a useful aid in the practice of their art

Principles of Roentgenological Interpretation By L R Sante MD Professor of Radiology St Louis University School of Medicine St Louis Missouri Cloth Price \$5 50 Pp 340 with 333 illustrations Ann Arbor Michigan Edwards Brothers Inc 1937

This textbook is printed in typewritten letters, and all the illustrations are given only by schematic drawings, nevertheless it is an excellent book for the beginner as well as for the expert in x-rays It is of greater value to be informed by clear drawings than by poorly reproduced pictures, since there is always a great difference between the original films and the reprints The author classifies the whole of roentgenology in twenty-three chapters At the end of each chapter, questions are given concerning its special content The index is rich Also suggestions are made for collateral reading The textbook is one of the best we have, and it is a good supplement to the author's book on roentgenologic technic

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Right of Trial Court to Order Physical Examination of Plaintiff in Personal Injury Action—The plaintiff sued the defendant for damages for certain injuries to her mouth, teeth and face allegedly resulting from an automobile collision which admittedly was due to the defendant's negligence At the trial, on the direction of her attorney, she exhibited her injuries to the jury The defendant then requested the court to require the plaintiff to submit to an examination by a dentist to be selected by the court to determine the amount of injury inflicted This the trial court refused to do, stating that it believed that it was without authority to do so From a judgment for the plaintiff, the defendant appealed to the Supreme Court of Oklahoma

In this case, said the Supreme Court, the sole questions for the jury to determine were the nature and extent of the plaintiff's injuries and the amount of damages to be awarded therefor Under these circumstances the exhibition by the plaintiff of the injured portions of her face and mouth could have had but one purpose, namely, to enhance the amount of damages to be awarded by the jury While the courts are in disagreement as to the authority to require a plaintiff to submit to an examination in the first instance, they are in practical unanimity with respect to the rule to be followed when the plaintiff has offered a portion of his body in evidence, holding that then the plaintiff's body becomes an exhibit in the case and that within reasonable limitations the opposite party has a right to make such inspection of it as will enable him to explain, criticize or impeach its value as evidence and to that end have it examined by experts The Supreme Court, holding that the trial court erred in not ordering the examination requested by the defendant, reversed the judgment of the trial court and ordered a new trial—*Isaac Tea Co v Ransdell (Okla)*, 69 P (2d) 69

Workmen's Compensation Acts Bell's Palsy a Compensable Injury—The claimant was employed as a saleswoman by the defendant department store While she was showing coats to a customer, a fellow employee switched on an electric fan and subjected the claimant to a sudden draft Bell's palsy resulted and the claimant filed a claim for an award under the workmen's compensation act of New York A disallowance of the claim by the state industrial board was affirmed by the supreme court, appellate division, and the claimant appealed to the Court of Appeals of New York

In this case, said the court, the claimant was struck by air propelled by an electric fan The result was "palsy which is limited to one side of the face and is acute in onset and called

Bell's" There was a consequent distortion of the parts and of the powers of expression. In the opinion of the court, the average man would say that so swift and harsh a disablement was an accidental injury when it was so strangely suffered in the ordinary day's work. It seemed to the court that analogy, too, leads to that conclusion. "Sunstroke, strictly speaking, is a disease, but the suddenness of its approach and its catastrophic nature have caused it to be classified as an accident." The order of the supreme court, appellate division, and the determination of the state industrial board denying compensation, were therefore reversed.—*Luyve v Stein Bros Department Store (N Y)*, 9 N E (2d) 828

Narcotics Possession of Growing Cannabis Plant Illegal—The appellant, Harris, was convicted of possessing unlawfully a certain narcotic drug, to wit, cannabis, and was sentenced to serve a term of three years in the state penitentiary. He appealed to the Supreme Court of Mississippi.

Two police officers of the city of Jackson, Miss., found a plant growing in Harris's back yard which they identified as cannabis. At the time the plant was discovered it was green and growing, about 7 feet high, and had seed pods or blooms on it. A Mississippi act makes it unlawful for any person to manufacture, possess, have under his or her control, sell, prescribe, administer, dispense or compound any narcotic drug except as authorized by the act. The terms "narcotic drugs" is defined to mean coca leaves, opium, cannabis, and every substance neither chemically nor physically distinguishable from them. Subsection (13) of section 2 of the act provides:

Cannabis includes the following substances under whatever names they may be designated: (a) the dried flowering of fruiting tops of the pistil late plant Cannabis Sativa L. from which the resin has not been extracted; (b) the resin extracted from such tops; and (c) every compound manufacture salt, derivative mixture or preparation of such resin or of such tops from which the resin has not been extracted.

Harris contended that the word "cannabis" as used in the act must therefore be limited to the substances as set out above, and that cannabis in any other form must be excluded. In other words, the contention was that the legislature intended only to make the possession of the "dried flowering of fruiting tops" a crime and not the possession of the green, growing plant. With this contention, however, the Supreme Court disagreed. By the use of the word "includes" in defining cannabis, the court said, the legislature clearly indicated that it did not intend to enact an entire definition. In the opinion of the court, the legislature intended to denounce as a crime the possession of cannabis in any form. The conviction of the appellant was therefore affirmed.—*Harris v State (Miss)* 175 So 342

Evidence Admissibility of Hospital Record—In the trial of a personal injury suit, a physician testified on behalf of the plaintiff as to the extent of her injuries and as to the treatment he had rendered. On cross examination it was shown that the physician treated the patient at a hospital. Thereupon the defendant introduced in evidence the hospital record, signed by the physician, containing certain statements inconsistent with the testimony of the physician in court. The introduction of this hospital record in evidence, said the district court of appeal, first district, division 2, California, was not error. If the physician had not testified at the trial the hospital record would have been hearsay evidence and would have been inadmissible in evidence. But since the physician did testify, the hospital record was admissible for the purpose of impeaching his testimony.—*Heiman v Marlet St Rl Co (Calif)*, 69 P (2d) 178

Hospitals Liability for Negligence of Nurse when Acting Under Supervision of Physician—When, said the Supreme Court of Oklahoma, a person employs a physician of his own choice and enters a hospital to receive treatment from the physician, and the hospital furnishes nurses to assist the physician under his supervision and direction, such nurses are the servants and agents of the physician while so assisting him. The hospital is not liable for their acts of negligence while acting under the supervision and direction of the physician.—*Randolph v Oklahoma City General Hospital (Okla)* 71 P (2d) 607

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

S 140 (Jan) 1938

- *Streptococcus Vaccines in Prevention and Treatment of Respiratory Infections Clinical and Experimental Study E C Rosenow and F R Heilman Rochester Minn—p 17
- Peripelvic Lymphatic Cysts of Kidney Review of Literature on Peripelvic Cysts J C Henthorne Rochester Minn—p 28
- *Wassermann Reaction in Infectious Mononucleosis Report of Case with Unusual Clinical Features B Hatz Brooklyn—p 39
- Venous and Peripheral Red Blood Cell Values Marjory I Andresen and E R Mudge Denver—p 46
- Spontaneous Rupture of Myocardium T K Rathmell Norristown Pa—p 52
- Histogenesis Classification and Identification of Cells of Blood and Marrow Based on Cultures and Hematologic Studies of Human Marrow and Blood E E Osgood Portland Ore—p 59
- Mechanism of Production of Acidosis S T Helms Baltimore—p 75

Vaccination Against Experimental Meningococcic Meningitis—Kolmer immunized guinea pigs, rabbits and monkeys with the subcutaneous injection of from three to five weekly doses of types I and III meningococcus vaccines cultivated in hormone broth for five days and sterilized with tricesol. All have shown the production of varying amounts of agglutinin. The serums of immunized monkeys also showed the presence of complement fixing antibody. Four weeks after the last doses of the vaccines the guinea pigs and rabbits were tested for acquired resistance by the intracisternal inoculation of living virulent meningococci. The monkeys were tested by the intraspinal inoculation of the organisms. All of twelve unvaccinated control guinea pigs died from severe meningitis in from twenty-four to seventy-two hours. Of twenty-eight vaccinated animals, five recovered. Of twelve unvaccinated control rabbits, ten died. Of twenty-eight immunized animals, fifteen died and thirteen recovered. All of six unvaccinated control monkeys showed moderately severe symptoms of meningitis but recovered. Of thirteen immunized animals, three probably showed symptoms of meningitis with recovery while the remaining ten remained entirely well. These results are believed to lend encouragement to efforts for the vaccination of human beings against meningococcic meningitis.

Streptococcus Vaccines and Respiratory Infections—Rosenow and Heilman placed large amounts of streptococci freshly isolated from colds and influenza in a menstruum of glycerin-saline solution in the hope that suitable preventive and curative vaccines might be thus available in advance of subsequent outbreaks of epidemic respiratory infections. Through the cooperation of physicians in various parts of the United States and Canada to whom the vaccine was sent they were able to make a further study of this inherently difficult and important problem. The persons vaccinated were chiefly those who were abnormally susceptible to recurring respiratory infections. In the great majority of the different groups representative of different climatic conditions the incidence of colds and of influenza was greatly reduced. A lesser number were slightly benefited and few were not benefited. There were eleven separate camps of the CCC in Minnesota, in each of which some of the men were vaccinated and some were not. In three other camps all men had been vaccinated and in ten additional camps, also in Minnesota none were vaccinated. The incidence of colds or influenza was consistently from a third to a half as great among the vaccinated as among the unvaccinated. In each of the fourteen subgroups of which some were and some were not vaccinated the vaccinated subjects fared better as

regards incidence, severity and duration of respiratory infections than did the unvaccinated controls.

Wassermann Reaction in Infectious Mononucleosis—Hatz, in treating a case of infectious mononucleosis, investigated the connection between a positive Wassermann test and a positive heterophile sheep cell agglutination test. Clinically the case was of interest because the complete absence of enlargement of lymph nodes or spleen, coupled with the age of the patient (41 years), could readily have led to a diagnosis of "influenza" or "grip" if proper blood studies had not been made. Serologically, a positive Paul-Bunnell test and a positive Wassermann associated with a negative Kline test were obtained. As the patient recovered, both the Paul-Bunnell and Wassermann tests became negative. This seems to point to a similarity in the mode of formation of the antibodies concerned.

- Lateral Vaginal Wall Retractor M C Piper Rochester Minn—p 169

Leukoplakia and Carcinoma of Cervix—According to Schiller, the relationship between leukoplakia and carcinoma is confused by the question as to whether the leukoplakia is not merely a precarcinomatous stage of the portio. The entire situation is thrown into further confusion by the improper use of the word "precancerous" or "precarcinomatous". The use of the word in diagnosis should be discarded, its use being restricted to symptomatic description. The diagnosis of the disorder that appears as leukoplakia should be made only on microscopic observation. The differences between the forms of leukoplakia can frequently be recognized with the naked eye or by a colposcopic examination. However, patches which differ slightly in color from the surrounding normal tissue may be overlooked during a hasty examination. In such cases iodine is useful. The application of iodine makes the grossly visible leukoplakia appear clearer and the latent leukoplakia visible to the naked eye. If there is a beginning carcinoma in the latent leukoplakia the iodine will reveal its presence even if other clinical methods fail. Cornification and carcinoma give rise to manifest or latent patches. This observation proves that there are leukoplakias which are definitely carcinomas, or at least carcinoid or carcinomatous epithelium. Leukoplakias which show definite carcinomatous changes and fulfil all of Schottlander's and Kermanner's criteria for carcinomatous 'beläge' are admitted as 'potential carcinomas' even by observers who are diagnosing carcinoma by invasion only. If in addition there is an invasive growth, even the most critical observer will be convinced that it is malignant. The only fact of importance is that the superficial carcinoma-

tous layer, which sometimes resembles a leukoplakia, may retain its superficial character for months or years before becoming invasive. The answer to the question whether such leukoplakias can become malignant is that they are already malignant. Leukoplakias formed through cornification should be differentiated in terminology. This can be done easily by borrowing a term from laryngology, in which similar changes are called leukokeratosis. Cornification may be incomplete or complete. The former is called parakeratosis and the latter keratosis. Excessive hornification is termed hyperkeratosis. Leukohyperkeratosis is a higher degree of leukokeratosis. A certain degree of cutaneous cornification is physiologic. However, a hyperkeratosis is pathologic. Leukokeratosis is used to denote cornification in general. The author has only once found areas of leukoparakeratosis or leukohyperkeratosis developing into carcinoma. There is no causal relationship between parakeratosis or hyperkeratosis and carcinoma of the portio. Advanced cornification, even the autonomous form, does not give rise to carcinoma. Areas of leukoplakia do not warrant radical treatment. A periodic examination is sufficient. These areas of leukoplakia are to be grouped with benign hyperkeratosis of the skin rather than with the leukoplakic areas of the mucosa of the mouth or larynx. A suggestive area of the portio when examined microscopically will turn out to be either a leukokeratosis or a carcinomatous layer ("belag"). The difference between the two is so marked that there is never a question of differential diagnosis. Proliferations of the epithelium, however, due to chronic inflammation do cause confusion sometimes.

Yeastlike Organisms Isolated from Vaginal Tracts—Jones and Martin isolated sixty-eight strains of yeastlike fungi from the vaginas of fifty-two pregnant and sixteen nonpregnant women. These strains have been identified and compared with type species of Benham and Stovall by developing a technic that can be carried out in a routine bacteriologic laboratory and that does not require special mycologic training.

Estrogenic Substances During Menstrual Cycle—Gustavson and his associates present the graphs of three women, all entirely normal from gynecologic and general points of view. Since a particular ovulation and developing corpus luteum are the controlling factors in the next subsequent menstruation, the relation that the peaks in the graphs bear to the time of the next menstrual period in each case were observed. Neither of the two peaks bears any constant relation to the time of the next menstruation, nor do they to each other. This variation is seen in the graphs of different individuals and in different cycles in the same individual. One of two conclusions is indicated: (1) Either the time of ovulation may vary considerably from cycle to cycle in the same individual, and be considerably different in different individuals, and the corpus luteum may require varying periods of time to reach its full development and activity or (2) the peaks of estrogenic excretion, presuming peaks of concentration in the blood, have no particular relationship to ovulation and corpus luteum activity. With the constancy with which these two peaks appear in the graphs obtained from daily twenty-four hour specimens in normal individuals, the first conclusion seems to be more logical.

Psychiatric Study of Car Sickness—Conn compared twenty-five car-sick children (thirteen girls and twelve boys) between 6 and 12 years of age with a group of twenty-five patients who were not car sick. The personality of the child and his life situation appeared significant in the occurrence of car sickness. All of the twenty-five car-sick children were described as being emotionally unstable, seventeen were timid and submissive in make-up. Among the complaints associated with the car sickness were restlessness, difficulty in falling asleep, nail biting, fear of the dark, enuresis and episodes of vomiting. Nineteen of the patients were found to be poorly nourished. Six children were of superior intelligence, five were of limited intelligence and fourteen were of average intelligence. The influence of the life situation was illustrated by a series of play contacts. In several cases the fears of the dark, general apprehensiveness and timidity improved in association with the disappearance of the car sickness. One child vomited while riding in a street car and in an automobile but was not disturbed while riding in a taxicab. Another patient was car sick only during the winter months. When the child was given a chance to express himself about his experiences on the street car and automobile, it was possible to begin to understand such reactions. In the verbatim reports of the play reactions there was no instance in which a car-sick child stated that the doll was at ease in the toy street car. Nor did a child who was not car sick report the anticipation of an accident or speak of the fearfulness of the doll in the toy street car.

Tuberculous Meningitis and Tuberculous Foci in the Brain—Beres and Meltzer made an anatomic survey of twenty-eight cases of tuberculous meningo-encephalitis and of two cases of tuberculoma without meningitis. In all cases of tuberculous meningitis there was an extension of the inflammatory process into the cortex resulting in foci of encephalitis, which varied in degree from perivascular infiltration to tubercle formation. In a few cases solitary tubercles were found but these were not in contact with the ependyma or leptomeninges. When tubercles

occurred in great numbers, they were due to direct hematogenous dissemination. Large solitary tuberculomas occurred with or without meningitis. Cortical tubercles which might have been responsible for the coexistent meningitis were demonstrated in only six cases. In eleven cases the choroid plexus disclosed the presence of tubercle formation. The changes in the blood vessels which were observed during the course of the study presented no observations that differed from those already described by other authors.

Rheumatoid Arthritis Treated with Bee Venom.—Kroner and his colleagues gave intradermal injections of bee venom (apicosan) to 100 patients with rheumatoid arthritis, seventy-three of these showed definite improvement, as judged by a fall in the corrected sedimentation index and an alleviation of the clinical symptoms. Seventeen were found to be entirely free from symptoms six months to a year after the treatments were discontinued, eighteen continued to have only mild transitory pains and thirty-eight were moderately improved. Ten of the patients studied had an advanced, active deforming type of arthritis and six of these showed moderate improvement. A patient was not considered improved unless there was a drop in the corrected sedimentation index, if previously elevated, as well as improvement in the clinical symptoms. Of the ten patients with advanced arthritis the number of injections for the six who improved was from eight to fifty-two, with an average of 31.5, while the four who failed to improve had from nine to twenty-eight, with an average of 18.5 injections. The duration of treatment for the former varied from two to fourteen months, and for the latter from two to four months. For the patients with a moderately severe arthritis the range of injections was from six to forty-eight and for the patients with a mild arthritis from six to thirty-eight. All injections were given intradermally. The site selected depended on the location of the most painful joints. The skin was cleansed with alcohol and wiped dry with benzene. The treatments were continued at weekly or biweekly intervals, increasing 0.1 cc at each visit. Only 0.1 cc was put into a wheal and the wheals were placed about 1 inch (2.5 cm) apart. When a patient had received 0.5 cc of concentration I, he was given 0.1 cc of concentration II, which was increased to 0.5 cc, and then concentration III was started. The dose was then increased 0.1 cc at each visit until the patient was receiving one ampule of concentration III. All injections were watched for five minutes. If large pseudopodia developed in the wheals, they denoted sensitivity and the dose was not increased for several visits.

Uric Acid in Gouty and Nongouty Individuals.—Jacobson employed the recent Folin method in the study of the uric acid in the serum of gouty and nongouty individuals. The analysis of serum derived from blood allowed to clot under

oil furnishes more valid data than does whole blood. The fasting uric acid in 100 nongouty persons consuming a mixed diet ranged from 19 to 67 mg per cent. In ninety-seven persons the uric acid in the serum was less than 6 mg per hundred cubic centimeters, it was determined on 177 occasions in twenty-one cases of gout, under various conditions. Its values ranged from 52 to 148 mg per hundred cubic centimeters. On 174 occasions the value exceeded 6 mg and on 167 occasions 7 mg. The consumption by gouty individuals of a purine-free diet during periods shorter than three months did not significantly influence the level of uric acid in the serum. The administration of acetylsalicylic acid, colchicine and salyrgan to gouty persons on several occasions was followed by an apparent temporary fall of the uric acid level. The uric acid in the serum, frequently determined in four gouty persons, exhibited marked fluctuation both during asymptomatic intervals and during attacks of acute gouty arthritis. An intensive study of one case over a period of one year demonstrated a significant fall of the mean uric acid level during a period of three days preceding attacks of acute gouty arthritis, during the attacks the level of uric acid in the serum remained unchanged. In four cases of gout there was an apparent direct correlation between the height of the level of uric acid in the serum and the severity of the disease.

Splenic Irradiation in Hemorrhagic Purpura.—In twelve patients with hemorrhagic purpura who received irradiation to the spleen, Jones and his associates found the response to roentgen therapy ineffective. An increase in platelets occurred in one patient but did not persist after further roentgen treatment. Many of the patients received 200 roentgens without favorable response. It seems probable that there are certain patients with this disease who will respond in a manner such as described by Mettler and others, and that there are other patients with the same disease who will fail to respond to adequate roentgen treatment. The authors' plan of treatment is as follows. If the patient is not in a dangerous state from loss of blood, they give him an opportunity to recover without any special form of treatment. If there is progressive anemia, small transfusions are used. These are given every two or three days or at times more often or in larger doses. Vitamin C is given intravenously in selected cases. Liver extract is given intramuscularly and orally. The use of snake venom and x-rays in sufficient doses is continued in all patients in whom it is safe and finally, when all other measures fail, splenectomy is resorted to. In one patient who had an acute intra-abdominal condition there was a sudden drop in red blood cells following roentgen therapy and in a patient with a long bleeding time intracranial hemorrhage developed and the patient died after roentgen treatment, probably as a result of retching and vomiting.

Mechanism of Shock.—Hepler and Simonds find that, when blood is impounded in the liver and gastro-intestinal tract by mechanical constriction of the hepatic veins in dogs, the systemic blood pressure falls abruptly to a level equivalent to from 35 to 70 per cent of the original pressure and is maintained for periods of at least thirty minutes. Injection of physiologic solution of sodium chloride during constriction of the hepatic veins in quantities more than the estimated initial blood volume induces a rise in systemic blood pressure during the injection, but the pressure falls almost to the previous low level within one to three minutes after the injection is stopped. The blood volume after injection of the solution and while the

hepatic veins are still constricted may be either greater or less than the calculated initial volume and the saline solution injected. Blood volumes after release of the hepatic veins were invariably much lower than the calculated initial volumes and the saline solution injected. The rate of fall in blood pressure and reduction in blood volume after injection of saline solution indicate the rapidity with which fluid escapes from the circulating blood when a considerable part of the total volume of blood is impounded in a known region of the body. Thyrotoxicosis in dogs adds a complicating factor in experiments of this type. In dogs submitted to injection of large amounts of saline solution much fluid was found to have escaped into the lumen of the stomach and into the gastric submucosa. The peritoneal cavity contained relatively little fluid, and the retroperitoneal tissues and the walls of the gallbladder and small intestine were moderately edematous.

Immunization with Scarlatinal Streptococcus Toxin

—Kern and his associates report their observations during the past two years on the intracutaneous injection of scarlatinal streptococcus toxin for the production of active immunity against scarlet fever. Their test subjects included 140 children from 16 months to 13 years of age, all of whom had been found to have a positive Dick test. Twenty-six of the children were frankly allergic. Scarlatinal streptococcus toxin, as prepared by a commercial house under license by the Dick scarlet fever commission, was used. The material was that usually employed in subcutaneous injection, containing 500, 2,000, 8,000, 25,000 and from 80,000 to 100,000 skin test doses respectively, per cubic centimeter. Each child was given weekly intracutaneous injections of toxin into the skin of the outer aspect of the upper arm. It was found that the intracutaneous injection of scarlatinal streptococcus toxin in about one-tenth the dosage employed subcutaneously will result in a negative Dick test in more than 90 per cent of susceptible subjects. Since the immunity so conferred would appear not to be as lasting as that by the full

subcutaneous dosage, those immunized by the intracutaneous method should be retested every six months and, if found Dick positive, should again receive a course of injections. The intracutaneous method has the great advantage of unusual freedom from severe general reactions.

Measles Inclusion Bodies —Broadhurst and her co-workers observed various morphologic types of inclusion bodies in measles blood taken from one day before the beginning of the rash to ten days after its appearance. These inclusion bodies are more satisfactorily demonstrated in blood smears by minimal staining with simple stains than with the customary complex blood stains. In blood smears inclusion bodies are readily demonstrable in the mononucleated types of white corpuscles. The inclusion bodies in measles blood smears include minute pinpoint bodies, somewhat larger globular bodies and compact densely staining masses sometimes definitely crescentic. While all types of white corpuscles may show shattered cells and disintegration changes, the mononucleated corpuscles show other distinctive characters: (1) the nucleus is paler than granule loaded cytoplasm when stained with methylene blue (2) the

margins are bubbly or eruptive and (3) occasional bizarre extensions or protusions are seen. Many of the tissue culture cells containing inclusion bodies are highly vacuolated and are often swollen and distorted in outline, showing both "ballooning disintegration" and "colliquation."

Hemolytic Streptococci from Normal Throats—Frisch found an incidence of forty (64 per cent) of group A streptococci in the throats of 621 normal adults of college age. Of 101 strains of hemolytic streptococci sixty-seven, or 66.5 per cent, lysed human fibrin, but only forty, or 39.6 per cent, were members of group A. Persons with intact tonsils harbored group A streptococci somewhat more frequently than persons whose tonsils had been removed.

Alpha Type Streptococci in Food Poisoning—Cary and his collaborators report a large institutional outbreak of food poisoning in which streptococci were present in enormous numbers in the incriminated beef croquettes. Filtrates and living cultures were fed to seven volunteers. Another green streptococcus isolated from coconut custard pie implicated in another outbreak was similarly fed. Diarrhea was the most prominent symptom and occurred among 117 out of 208 young men. Their experience with human volunteers has indicated that living cultures of alpha type streptococci, and not filtrates, are necessary to give rise to symptoms of food poisoning in man. The incubation period corresponds to that in *Salmonella* type food poisoning (twelve hours), which is caused by living organisms, rather than the staphylococcal type (three hours), due to soluble enterotoxin substance.

Blood Coagulation Factors in Hemorrhagic Disease

—In two infants with hemorrhagic disease of the new-born, Sanford and Leslie found the faulty coagulation to be due to a failure of the platelets to disintegrate. This is a qualitative platelet dysfunction and is an exaggeration of the platelet action in blood of the normal new-born infant. There was no evidence that small intramuscular injections of blood from the parents had any effect on the coagulation time of the blood of twenty normal new-born infants. One of the infants with hemorrhagic disease recovered after a small injection of the father's whole blood intramuscularly. The second infant recovered without treatment of any kind.

Tuberculin Sensitization by Intracutaneous Injection

—Nelson and his colleagues tried to determine whether tuberculin in amounts as great as or slightly greater than ordinarily used for skin testing is capable of inducing sensitization to itself in man. If this were the case tuberculin testing after the initial injection would be valueless for the detection of tuberculous infection. Their evidence does not support the theory of artificially induced tuberculin sensitization by single or repeated intracutaneous tuberculin injections for the following reasons: 1. The third injection was performed ninety-six hours after the first test, an interval presumably too short to permit induction of sensitization. 2. A consistent individual

response was not obtained. 3. Neither were consistent maximal rates or sizes of reactions obtained in later tests. 4. X-ray evidence, usually accepted as diagnostic of tuberculous lesions, in children of all groups who had no or only questionably positive reactions in the first two tests indicated that tuberculous lesions may be associated with a low degree of tuberculous allergy. This does not imply that sensitization to tuberculin or tuberculo-protein is impossible, but such sensitization does not appear likely from the ordinary use of tuberculin for purposes of cutaneous testing.

Herpetic Stomatitis—In the last eleven years Dodd and her associates have seen in the Vanderbilt Hospital Children's Clinic eighty-eight cases of a form of stomatitis which appears to be a clinical entity. The disease occurred in children from a few weeks to 14 years of age but was far more common in children between the ages of 1 and 3 years. The disease was apparently contagious, as sometimes two cases were seen in the same family or there was a history that the patient had recently been in contact with a child having a similar condition. The stomatitis was apparently identical with that described in most pediatric textbooks as aphthous stomatitis. There appears to be a sudden onset of illness with fever, general malaise and loss of appetite. Either with the onset of fever, or twenty-four hours or more later, lesions appear in the mouth. When these were seen early, they consisted of reddish blisters of the mucous membrane. Soon the blisters became ulcerated and the ulcers were covered by a yellowish white membrane. The commonest sites of the lesions were the tongue, the inner surface of the lips and the buccal and sublingual mucous membrane. In every instance there were, besides the local lesions, marked redness and swelling of the gums with a tendency to bleed easily. Salivation was greatly increased. The older children complained of soreness of the mouth and pain on eating; the younger ones were irritable and often refused to eat or drink anything. Smears of material from the mouth and gums showed no predominating organism. Spirochetes and fusiform bacilli were almost always absent from the localized lesions but were found quite commonly in smears taken from the swollen gums. Cervical adenitis of a well marked degree was noted in fourteen children, a palpable spleen in one and diarrhea in six. Five children had an accompanying herpes of the skin of the lip and two had paronychia with lesions which looked like herpes. Four also had pneumonia, one dysentery, one diphtheria and one influenza bacillus meningitis. The disease appeared to be self limited in nature and lasted from a few days to two weeks. Swabbings from the lesions in the mouth of twelve unselected patients were inoculated immediately onto the scarified cornea of a rabbit in order to prove the presence or absence of the virus of herpes. Typical herpetic vesicles developed within twenty-four to forty-eight hours followed by a purulent keratoconjunctivitis. Usually the virus was transferred to a second rabbit, which was killed at the end of twenty-four hours. Immunity was demonstrated in six of seven rabbits which survived the infection.

Nasopharyngeal Infection—O'Connor discusses fifty-five cases of nasopharyngeal infection. The three most common complaints, in addition to fever and fatigue, were headache, loss of weight and aching of muscles. Thirteen of the patients were

known to have had a persistent leukocytosis and one patient had leukopenia. The ages of the group varied from 5 to 57 years. The duration of symptoms before patients were seen ranged from two weeks to seven years. There was no evidence of sinus infection except in four patients. The turbinal mucosa appeared perfectly normal. No secretion was present in the region of the natural orifices of the accessory sinuses. Transillumination of the maxillary sinuses was brilliant. X-ray studies of the sinuses, made in the majority of cases, were normal. Thirteen showed evidence of chronic but slight infection of the tonsils and 25 per cent showed hypertrophy of the lateral wall of the pharynx. The ears, structures of the nose and larynx were without significant abnormalities in all the cases. Inflammation of the nasopharynx of varying degree was found. In many cases it was localized in the remains of the pharyngeal tonsil. In others a diffuse inflammation of the whole nasopharyngeal area was present. A third group showed a localized inflammatory area on one wall or the other. A cultural study in most of the cases confirmed the presence of definite infection. While the bacteriologic studies confirmed the clinical and physical observations in the majority of cases, there were some that did not coincide. The infection may be situated deep in the tissue so that the responsible bacteria are not obtained in a culture taken from the surface. The symptoms may disappear when drainage is enhanced or absorption decreased, even though organisms still are present in large numbers. The cultures were particularly valuable in determining the type of treatment to be used, since dyes and other germicidal agents vary markedly in their effect on different bacteria. The local treatment consisted of direct application to the involved area of a solution of silver nitrate of varying strength, depending on the degree of congestion, or, in some instances, of a weak solution of zinc sulfate. This was followed by generous application of a 2 per cent aqueous gentian violet solution or a 2 per cent solution of methylene blue. When there was no response to this treatment, a 0.5 per cent solution of colloidal iodine was used, followed by the dye, and when there was no relief an autogenous filtrate was made, combined with a water soluble base and applied directly to the area. Usually, during the course of local treatment, the patient was instructed to use saline irrigations and mildly antiseptic drops. The number of treatments required to clear up the infection was dependent on the species of organism present. In most cases the focus was eradicated with from six to twelve treatments. Nine of the fifty-five patients failed to respond to treatment. Patients who do respond may be subject to reinfection with return of symptoms but then respond to treatment much more readily than in the initial attack.

Staphylococcal Septicemia Treated with Antitoxin—

In a review of the four cases that Parker presents certain salient features deserve especial mention. The treatment of staphylococcal septicemia is far from satisfactory. General

supportive measures, transfusions at frequent intervals and the drainage of free pus whenever found still remain the foundation of all successful therapy in these infections. In each of these four cases such measures were instituted and in each instance the clinical course justified the conclusion that the early death of the patient was only a matter of time. Staphylococcus antitoxin was then added to the program, with brilliant results in three of the four cases. The cardinal features of severe staphylococcal infections were present in these cases. A rapidly progressive anemia requiring frequent transfusions, the phenomenon of venous thrombosis, the ultimate dissolution of the thrombus with septicemia, tissue invasion, toxemia, pulmonary metastasis and the like are readily explained in terms of a pyogenic organism with an exotoxin which is hemolytic, dermonecrotic, thrombophlebitic and, in sufficient dosage, lethal. The thrombophlebitis must be regarded as an essentially protective mechanism on the part of the host.

Serum Phosphatase—In attempting to explain the mechanism involved in the elevation of serum phosphatase in pathologic conditions, Maddock and his associates find that the most significant conclusion of clinical import that can be drawn from previous experiments is that what has always been regarded as an increase in amount of serum phosphatase in disease is not an actual increase in enzyme but merely an activation of preexisting enzyme normally present. This necessitates an alteration in the fundamental concept of phosphatase in both normal and pathologic states. The relation of serum phosphatase and bone phosphatase to the growth and repair of bone may well be involved. The mechanism of increased serum phosphatase in jaundice seems to be understandable in that any obstruction to the excretion of bile results in the damming up of both depressing (bile acids) and activating (cofactor) substances. Since the cofactor is more powerful as an activating agent than bile acids are as depressors, the net result is an increase in activity of serum phosphatase. The difficulty of attempting to use phosphatase determinations in the differential diagnosis of liver disease is thus apparent. Phosphatase activity must represent the outcome of reactions in a complex system consisting of enzyme, cofactor, oxidation-reduction potential and substrate. Thus the phenomenon is analogous to the cozymase system described by Warburg and von Euler. Human disease may originate from disturbances in enzymatic activity either from a deficiency or from an excess of any of the factors in the system.

Fulminating Hemorrhagic Purpura—Denninger discusses two cases of fulminating hemorrhagic purpura. The cases were strikingly similar and suggest a possible familial tendency. The one occurred in a male child of 3 and the other in his aunt of 16 years. The etiology was doubtful thrombocytopenia was suggested. In the child the first symptom occurred about 4 o'clock in the morning and was followed by death in eleven hours. In the second patient, evidence of definite symptoms started at 5 o'clock in the morning and had a lethal termination eight and one-fourth hours later. Signs of cerebral irritation (hemorrhage) were prominent in both as judged by pupillary reaction clonic and tonic spasms, vomiting and diffuse abnormal body sensations. Scurvy may be ruled out on the basis that there was no evidence of dietary deficiency and the absence of large hematomas under the peritoneum or in the deep muscles of the body. Poisoning or drug reactions also were eliminated. Blood studies revealed nothing abnormal indicating that a deranged thrombogenic mechanism was present and that these cases belong in the category of the true idiopathic purpuras of unknown etiology.

Treatment of Venereal Lymphogranuloma with Diluted Frei Antigen—In fifty-four cases which gave positive Frei reactions, there were only three without characteristic clinical signs and history. Accordingly Anderson and Harnos have found the Frei test to be specific in 94.5 per cent. They observed discrepancies in certain cases when tested by various potent Frei antigens, also some differences in the microscopic appearance, which seem to support the opinion that there are at least two subgroups of the disease. The treatment in their forty-eight cases of venereal lymphogranuloma is presented. They feel that the use of diluted Frei antigen, administered intradermally, has demonstrated encouraging results and that its use should be continued with further study. The use of Frei antigen as a vaccine in treatment was not familiar to them in November 1935, when they began this type of treatment at the Norfolk Marine Hospital. They decided on the intradermal administration of the vaccine as a route more effective than subcutaneous or intravenous treatments. The sterile and potent Frei antigen, diluted four times, was found an effective agent in treatment. The resulting vaccine has been a 1:24 or 1:28 dilution of the heat treated pus in physiologic solution of sodium chloride. This diluted Frei antigen is the only type of treatment received by the authors' lymphogranuloma patients, plus occasional lymphadenectomy, incision and drainage. They administer the diluted antigen on the nonhairy surfaces of the thighs, at intervals of five days. The initial dose is 0.05 cc, which is increased at each dose by 0.05 cc up to the maximal dose of 1 cc. The treatment is continued until the sinuses heal and the adenopathy subsides, or, in case lymphadenectomy was performed, until the wound heals, requiring from six to twelve doses of the vaccine. In general, the clinical response to the vaccines consisted of gradual reduction in the size of the gland to only a small indurated area within a period of from one to two months. The treatment prevented the formation of new fistulas, induced within a week a beginning reduction in the size of the glandular enlargement, and materially shortened the time required to close an operative wound.

Death in Liver Peritonitis—Martin and Trusler believe that the putrefactive pressor bases, tyramine, iso-amylamine, phenylethylamine and histamine-like substances, are rapidly produced by the action of bacteria on liver substances during the process of incubation. Whether or not the amines with pressor effects on the blood pressure predominate over the amines with depressor effects depends on the kind of bacteria present in the digests. These toxic amines and other heat-stable, water-soluble, toxic substances formed in the process of incubation of dog liver were lethal when the equivalent of 200 to 300 Gm of incubated liver was given slowly intravenously to an anesthetized dog. When injected intravenously into a

dog without anesthesia, the equivalent of 100 Gm of incubated liver was sufficient to cause rapid death. The terminal event is convulsive seizures. In addition to other factors, putrefactive amines may also contribute to the rapid death of dogs subjected to liver peritonitis. It is conceivable that deep-seated infections in human subjects may give rise to toxic amines which enter the general circulation and contribute to the shock syndrome frequently associated with such infections.

Cutaneous Healing in Wounds—Conway declares that for a surgical incision and suture to have a direct effect on the degree of fibroblastic response in a clean incised wound and also on the ultimate cosmetic result the incision should be made parallel to Langer's lines of elasticity of the skin. In operations about the face and neck, the direction of these lines of elasticity is easily observed since they can be defined through facial grimace. However, in operations on the abdomen and extremities, primary importance is attached to exposure of the wound and attention rarely is paid to the direction of the incision as regards cutaneous tension. It is important to hold the skin taut while it is being incised so that incision may be made sharply at a right angle to the flat cutaneous surface. If this is not done the operator may divide the layers of the skin in an oblique plane—the so-called beveled incision. It is difficult to suture accurately the edges of such an incision in close approximation. When fine arterial silk threaded on small straight needles of the milliner's type is applied with the on-end mattress stitch, ideal approximation of the cutaneous margins may be achieved. Crepe lisse dressing as advocated by Halsted impregnated with collodion and applied directly to the surface of the skin or, if the wound is not healed completely, over a layer of silver foil is an invaluable aid in limiting the stress on a sutured wound when it is in the early stages of healing and before its maximal tensile strength has been reached.

Placental Blood for Transfusion—Goodall and his associates find that the placental blood furnishes an unfailing source of supply for transfusion. When the baby is born it is laid on the mother's abdomen. The cord is tied or clamped and wiped clean with a sponge moistened in 75 per cent alcohol. The cord is stripped free from blood for about 6 inches. The cord is cut with sterile scissors and the severed end is lowered below the vulva. A special towel with a 2 inch hole in its center is put over the hand holding the cord in such a manner that the hand is opposite the hole. The towel is clamped to the operator's gown near the elbow with an Allis forceps. The end of the cord is passed through the aperture in the towel and so placed that its end hangs in the funnel of the receptacle held

by the nurse. Pressure on the cord is then released completely and the blood is collected. Pressure on the fundus by the nurse or assistant hastens the emptying of the placenta. When completed, the cord is clamped. The process occupies about three minutes, and the average amount collected from each patient may vary from 100 to 150 cc. Blood grouping and Wassermann reactions receive due consideration and blood is always available when it is needed for transfusion. The preservative (suitable for sixty days) that has been found to be most suitable is that proposed by the Moscow Institute of Haematology and consists of 7 Gm of sodium chloride, 5 Gm of sodium citrate, 0.2 Gm of potassium chloride, 0.004 Gm of magnesium sulfate and 1,000 cc of twice distilled water. The solution is put up in ampules of 25 cc, which gives the proper dilution when added to 100 cc of distilled water. The preservative and blood from each case are mixed in approximately equal proportions. Preserved blood has many advantages over fresh blood. Food and other extraneous allergic reactions are eliminated. Certain individuals absorb a large quantity of unsplit proteins during digestion and these are capable of being neutralized by the allergins of that specific person, but the recipient may not be so fortunate, and, if not, an allergic reaction must follow. In preserved blood, autodigestion occurs and allergic reactions do not occur after forty-eight hours of preservation. Before transfusion, the fetal blood should be heated in a basin of water and shaken before transmission. It should be filtered through two layers of sterile gauze. Two or more fetal bloods may be given simultaneously, if necessary, after separate matching.

Tendon Transplant for Patella—Hauser classifies and divides recurrent dislocations of the patella into three clinical types: congenital, traumatic and rachitic. An operation is described which is original in that it fulfils all the prerequisites of satisfactory correction: (1) it prevents recurrence of the dislocation, (2) it gives the patient a feeling of absolute security, (3) it reestablishes the functional capacity, (4) it gives the knee a normal appearance, (5) the risk to the patient is minimal and (6) the convalescence is short. Illustrative cases are reported. The method has been in use for five years and the results have been uniformly satisfactory. The technique of the operation referred to is as follows: A curved incision is made, starting above the upper lateral margin of the patella, curving laterally around the patella and coming back to the midline about half an inch below the tubercle of the tibia. The skin is freed on both sides to expose the patella, the conjoint tendon and the patellar ligament. The patellar ligament is then dissected free down to its insertion. A block of bone about one half inch square, including the attachment of the patellar ligament, is removed from the tibia by means of the electrical saw on three surfaces and an osteotome on the upper surface under the hyaline cartilage. The entire lateral side of the patella is then dissected free by dividing the fascia down to the capsule. The dissection is carried along the lateral side of the conjoint tendon, well up into the area of the fascia lateral to the vastus muscle, thus thickened fascia is divided down to the capsule but the operation remains extra-articular. The patella can now be drawn medially. The insertion of the patellar ligament is drawn to the median side of the tibia and distally until the patella lies low in the normal position between the condyles. The periosteum is incised to make two flaps, which are reflected. Then a bony block half an inch square is removed from the tibia in this area. The attachment of the patellar ligament and its block are countersunk in this space, and the periosteum is then sutured over the block. The second graft is fitted into the space at the tibial tubercle. Three sutures of No. 1 chromic catgut act as further stays to hold the medial side of the patellar ligament to the periosteum. The stretched medial fascia is then reefed in the region of the upper margin of the patella. The skin is closed. The fixation is held by means of a cast of plaster of paris for from ten to fourteen days. The sutures are removed at the end of this period, after which the quadriceps muscle can be massaged and weight bearing started with the leg extended. The fourth week after the operation has been performed the knee can be flexed and the quadriceps muscle allowed to contract voluntarily. Free flexion is permitted after six weeks.

Compression of Chiasma, Optic Nerves and Optic Tracts.—According to the clinical classification of Bramwell, intracranial aneurysms may present themselves as apoplectic and paralytic. It is with the latter only that Jefferson deals, and of these only with such as have affected the visual apparatus, that is, by compression of the optic tract, chiasma or optic nerve. Of fifty-three intracranial aneurysms there were sixteen of pure subarachnoid hemorrhage (with nothing to indicate the precise site of the aneurysm), nine aneurysms with paralysis of cranial nerves (usually the third nerve), sixteen sacular (nonfistulous) aneurysms of the internal carotid in the cavernous sinus and twelve basal aneurysms with disturbance of the visual pathways. These last twelve cases are reported after being grouped under four headings: (1) those interfering with the optic radiation and striate cortex, three cases, (2) those compressing the optic tract, one case, (3) those affecting the optic nerves, two cases, and (4) those involving the chiasma, six cases. Of the first group the sudden onset of the disorder and the nonprogressive nature of the clinical pictures leave no doubt that two are examples of thrombosis of the posterior cerebral artery and the third of thrombosis of some part of the middle cerebral. In all these cases the immediate clinical picture was that of subarachnoid hemorrhage. The pathology of the type of aneurysms under discussion seems in no way to differ from that of the so-called berry aneurysm. In general they occur like other aneurysms, at the bifurcation of a large vessel, in this case the internal carotid, perhaps where the ophthalmic artery leaves it or, in the suprachiasmatic group, at the point where the anterior cerebrals are joined by the anterior communicating branch. The differential diagnosis of a chiasmal lesion rests on the nature of the field defect coupled with the manner of its evolution and the rapidity of its development, the degree of pain associated with the evolution of the visual defect, the coexistence of other neurologic signs, the presence or absence of tubercular or endocrine disturbance and the x-ray evidence. There is only one useful treatment for these cases, and that is carotid ligation.

Outbreak of Acute Respiratory Infection in Neonatal Ward Alice E Dickie—p 139

The Heart in Diphtheria.—The prevalence of severe diphtheria in Hull during the last six years has given opportunities for the observation and study of the toxic effects seen in this

disease. Leete attempts to classify the varying degrees of myocardial damage with a view to prognosis and management of the cases, based on a series of 4,700 cases of faucial diphtheria, which included 461 deaths, mostly toxic, and 452 cases of nonfatal paralysis. The large number of toxic deaths is due chiefly to the high incidence of virulent strains of *Corynebacterium diphtheriae* during this time. The majority of toxic deaths occurred within the first fifteen days of disease. In all these cases the heart is undoubtedly affected, but when death occurs early, during the first week, cardiac phenomena are not prominent and are so overshadowed by the general poisoning that one is inclined to say that these early deaths are due to general toxemia. Later, from the seventh to the fourteenth day of disease, cardiac symptoms and signs are more in evidence and the impression given is that death is due to cardiac or circulatory failure. Late cardiac deaths associated with paralyses in the fifth and sixth week have not been seen. Cardiac signs are slight and similar to those encountered in any very severe toxemia. Severe cases will certainly necessitate seven, eight or even twelve weeks in bed and this treatment must be given. But mild and moderate cases that have not given the indications of toxemia require no further treatment by the end of the fourth week and the patients may safely be sent home. Absolute rest is still all important in the cardiotoxic cases. Whether any drug influences this condition for good is open to doubt. Survival depends on the amount and distribution of undamaged or lesser damaged myocardial tissue and it is difficult to see how the stimulation of this modicum is helpful. Conservation should be the aim, the control of vomiting in toxic cases by dextrose and insulin, and the careful use of morphine to secure the all important rest are indirect methods of cardiac treatment that mean more to the patient than any cardiac drugs.

Virus of Venereal Lymphogranuloma.—Okanishi finds that the cerebrospinal fluid of mice infected with the virus of venereal lymphogranuloma is turbid and viscous. It contains numerous cells, from 2,000 to 4,000 in 1 cc of fluid, most of which are lymphocytes. The brains of infected mice were washed with sterile saline solution, and the supernatant fluid was obtained by centrifugation of the washing. Even the intracerebral inoculation of the fluid in a dilution of 1:10,000 into healthy mice caused the typical symptoms of the disease to appear, which fact shows that the supernatant fluid contained the virus in abundance. This method of obtaining the fluid almost free from impurities, yet with a high content of the virus, will greatly aid in the investigations on the virus of this disease.

Limits of Prevention of Tuberculosis in Human Species by Means of Calmette Guérin Vaccine B Weill Halle—p 209

*Treatment of Painful Crisis of Gastroduodenal Ulcer by Small Doses of Histamine A Jacob and L Israel—p 210

Histamine in Treatment of Painful Crisis of Gastric Ulcer—Jacob and Israel direct attention to the histidine treatment of ulcers of the digestive tract which was introduced by Weiss and Aron. After reviewing the theory of histidine deficiency, on which this treatment is based, they show that the ampules of 4 per cent solution of histidine which were utilized for the treatment of gastric ulcers between 1933 and 1935 contained traces of histamine. Because there were indications that these traces of histamine, approximately 0.1 mg per ampule, were the effective factor, the author resorted to the subcutaneous injection of 0.1 mg of histamine in patients with ulcers of the digestive tract. They report the clinical histories of seventeen of the thirty-eight patients with gastric ulcer in whom they employed the daily injection of 0.1 mg of histamine. The histories indicate that the usual number of injections was ten, in some the number was smaller and in others it was larger. In all these cases the pain of the ulcer disappeared, often after the third injection. Discussing the mode of action of the histamine treatment, the authors mention the vasodilatory effect on the capillary system in general, and particularly on that of the gastrointestinal tract, the contracting action on the smooth muscles of the digestive tract and the remarkable antalgic power of histamine. They point out further that, if histamine is so effective against the painful crises of ulcer, it is likely that it exerts also a therapeutic action on the ulcer itself. They think that a cicatrization of the ulcer might be possible but insist that so far this is still in the domain of hypothesis.

Velocity of Circulation in Heart Diseases T Sessa—p 2

*Treatment of Heart Diseases by Antithyroid Roentgen Therapy T Galli—p 32

*Relation Between Velocity of Circulation and Basal Metabolism in Heart Diseases E Ascarelli—p 44

Treatment of Heart Diseases by Roentgen Therapy of Thyroid Region—Galli states that roentgen irradiations of the thyroid region give better results than thyroidectomy in the treatment of heart diseases. The treatment induces a controllable diminishing hypofunction of the thyroids with consequent improvement of the cardiovascular function and of the decompensation of the heart. It is harmless and not followed by myxedema. In administering the irradiations he divides the thyroid region into three imaginary fields which correspond to the right and left lobes and to the isthmus. The irradiations are given through a filter of 0.5 mm of zinc and 2 mm of aluminum. The first six treatments are given daily. The second six are given every other day. Only one field is irradiated at a time. The treatments are given in succession to the first, second and third fields at a dose of 300 roentgens for each irradiation. The first and second series of six treatments each are followed by a period of temporary discontinuation for two or four weeks, according to the absence or appearance of an erythematous reaction and then repeated by the same technique up to a total, which varies from three to four series. If the patient suffers from cutaneous hypersensitivity the treatments are given at longer intervals. The author has treated several cases, one of which is reported. Up to the present, three months after discontinuance of the treatment, the satisfactory results obtained are lasting. The article is a preliminary note.

Relation Between Velocity of Circulation and Basal Metabolism in Heart Diseases—Ascarelli determined the velocity of circulation and the basal metabolism of fifty-eight patients who were suffering from heart diseases. In decompensated heart diseases the velocity of circulation is diminished and the basal metabolism is increased. The variations are proportional to the intensity of decompensation. However, there are frequent exceptions. An increase or diminution of the basal metabolism which is proportional to those of the velocity of circulation shows better clinical conditions of the

patients than the presence of a basal metabolism and a velocity of circulation which follow opposite directions in increase and decrease, respectively. The author searched for a direct proportional ratio of the tests and obtained a product which he calls coefficient of velocity of circulation and basal metabolism. The figures of the coefficient are proportional to the evolution of the clinical condition. The coefficient increases as the clinical conditions are aggravated and decreases as they improve. The coefficient is of prognostic value and more reliable for decompensation of the heart than the results of the velocity of circulation or of the basal metabolism by themselves.

*Zambrini's Ptyaloreaction in Surgery C. Scartozzi—p 99

Zambrini's Ptyaloreaction in Surgery—Zambrini's reaction for the diagnosis and prognosis of vital resistance, its technique and several of its applications have been described in various medical journals, especially French and Italian and in *THE JOURNAL*, Nov 14, 1936, page 1679. The test is based on the changes of saliva produced by the addition of a coloring reagent and measured by a standard colorimetric scale. According to the literature, the color of saliva in the light shades (low figures in the scale) indicates a diminished vital resistance or poor evolution of the course of the disease, whereas dark shades (high figures in the scale) indicate good vital resistance and satisfactory evolution of the disease. Scartozzi made the test in fifty cases in which operation was to be performed. He found that before the operation the saliva of patients in normal condition, except for the presence of the surgical condition (hernia or varicocele), gives high figures in the colorimetric scale, while that of patients in poor nutritional and general condition or with disturbed crasis of the blood (appendicitis, gastro-duodenal ulcer and cholecystitis) gives low figures in the scale. The immediate and following postoperative reactions of the patients do not show any relation to the figures given by the test before the operation. The figures in the chromatic scale diminish in all cases after the operation and return to preoperative figures in from three to five days after the operation unless local or general complications develop. There is no relation between the type of anesthesia used in the operation and the behavior of the vital resistance during and after it. The author concludes that Zambrini's test shows the actual vital resistance of the patient but does not have any prognostic value. The reaction takes place by deviations of the pH of saliva from the neutral point to the acid or alkaline zones. Zambrini's fluid is an indicator. The pH of normal saliva is in the alkaline zone in Zambrini's scale. A reaction showing increased acidity of saliva shows a tendency to acidosis and a diminished vital resistance. The reaction shows the actual but not the total acidity of saliva. The latter can be ascertained by the sensitivity of the pH of the saliva to be displaced from one to another zone around the neutral point when a certain number of drops of decinormal solution of acids or bases, which varies from 1 to 14, is added to the saliva. The larger the number of drops that are necessary to displace the pH of a given specimen of saliva, the more intense the total acidity of the saliva. According to the author the determination of total acidity of the saliva is of value in estimating the final results of the reaction for the vital resistance.

*Test of Hippuric Acid in Liver Diseases E. Ascarelli—p 225

*Treatment of Echinococcal Cyst of Lung by Artificial Pneumothorax Case G. Roberti—p 233

Hippuric Acid in Liver Diseases—Ascarelli followed the behavior of the elimination of hippuric acid through the urine during the first four hours subsequent to administration of 6 Gm of sodium benzoate by mouth as a test for function of the liver in synthesizing hippuric acid. He carried on the

test in ten normal persons and in forty-one patients who were suffering from liver diseases. He found that the total amount of hippuric acid eliminated in the urine of normal persons during the test is about 3 Gm. The amount of hippuric acid eliminated during the test by patients who are suffering from liver diseases with involvement of the liver parenchyma (toxic and hepatic jaundice, cancer or metastases of the liver and atrophic cirrhosis) is diminished. It is almost normal in patients who are suffering from diseases of the biliary tract, with or without jaundice, syphilis, with or without splenomegaly and jaundice, in certain forms of nonatrophic cirrhosis of the liver and in cardiac diseases with a stasic liver. The amount of hippuric acid eliminated during the test varies according to the improvement or aggravation of liver insufficiency. However, low figures of elimination of hippuric acid do not show a fatal evolution of liver diseases, as the results of the test show insufficiency only of the detoxicating function of the liver. The test is of an easy technic and of diagnostic and prognostic value. It is advisable to use it as a complementary test or the function of the liver.

Echinococcic Cyst of the Lung—Robert's patient, aged 18 years, showed clinical symptoms simulating tuberculosis. The roentgenograms of the lung were similar to those of cavitation of the tuberculous lung. The sputum gave negative results for tubercle bacilli. In the course of artificial pneumothorax an echinococcic cyst was eliminated during coughing. The patient gave positive results to the Casoni test. The air insufflations were followed several times by coughing and elimination of echinococcic membranes up to complete elimination of the cyst and recovery of the patient as collapse therapy took place.

Significance of Achylic Chloranemia in Gynecology—Hildebrandt thinks that knowledge about achylic chloranemia is not sufficiently disseminated and that the disorder does not receive the attention it deserves. The varying interpretation of the leading symptoms of the disorder are the reason why so many different terms have been applied to the disorder. In the German literature, achylic chloranemia and essential hypochromic anemia are the most commonly used terms. The disorder is much more frequent in women than in men. Most statistics agree that 80 per cent or more of the patients are women. It is said that the age groups between 30 and 50 years are most subject to it. The patients frequently complain of fatigue, lack of energy, palpitation, tinnitus aurium, attacks of fainting, painfulness of the bones, loss of weight and gastrointestinal disturbances, such as lack of appetite, flatulence, constipation or, more frequently, diarrhea. Other symptoms are burning sensations along the esophagus with difficulty in swallowing, burning of the tongue, paresthesias, particularly in the terminations of the extremities, and even slight disturbances in walking, all of which are symptoms that in a more severe form appear in pernicious anemia, to which achylic chloranemia seems related. The objective symptoms are likewise similar to those of pernicious anemia: there are changes in the lingual mucosa, trophic disturbances in the appendages of the skin, particularly of the nails, and rhagades. The skin is often pale white. The chief symptom of achylic chloranemia is a disturbance in the secretion of the gastric juice. Examination of the blood is of great importance for the diagnosis of the disease. The principal symptom is the hypochromia. The number of

erythrocytes is often decreased. After pointing out that achylic chloranemia may be accompanied by circulatory disturbances, the author gives his attention to menstrual anomalies and genital hemorrhages that may appear during this type of anemia. He says that Schulten, on the basis of fifty cases, estimated the incidence of severe menstrual hemorrhages in achylic chloranemia at approximately 75 per cent. He himself, having observed only six cases, is unable to give definite percentages, but he gained the impression that menorrhagia and metrorrhagia not only occur in achylic chloranemia but may dominate the clinical picture. He describes the clinical histories of patients in whom this was the case, but he also says that menstrual anomalies were absent in two of the cases of achylic chloranemia that he observed. Iron therapy is the method of choice in achylic chloranemia. He administers reduced iron, giving 1 Gm three times daily, and in order to intensify the action of the iron he also gives hydrochloric acid. The iron therapy must be continued until a considerable improvement is noticeable in the blood status. The menstrual disturbances or genital hemorrhages that may exist improve simultaneously with the blood status under the influence of the iron therapy.

Action of Sulfanilamide in Gonorrhea—Felke reports investigations that were conducted in order to explain the therapeutic action of some sulfanilamide preparations in gonorrhea. He finds that nearly all investigators agree that the pathogenic organisms are somehow impaired by the sulfanilamide and thus are made vulnerable for the defense powers of the organism. The sulfanilamide preparations that he used were several preparations identified by numbers. In summarizing, he says that the sulfanilamide compounds that are effective in the therapy of gonorrhea inhibit the growth of gonococci in the test tube when used in the same concentrations that are reached during the therapy in the organism. In some strains of gonococci there is no inhibition of growth with these concentrations, but considerably more sulfanilamide has to be added in order to inhibit growth. These sulfanilamide-fast strains of gonococci generally are derived from patients who are resistant to this chemotherapy. From the results of control cultures on patients it is concluded that this different behavior of the gonococci is a result of the immunity status of the organism. Strains of gonococci can be made sulfanilamide fast in culture experiments. Testing strains of gonococci obtained from patients in culture mediums that contain sulfanilamide preparations is occasionally helpful in deciding on the best chemotherapy.

Pancreatropic Hormone in Acute Pancreatitis—After discussing the disturbances that exist in acute pancreatitis, Wustmann directs attention to the discovery by Anselmino and his associates of a pancreas-stimulating substance in the anterior lobe of the hypophysis. Inspecting microscopic preparations of the pancreas of animals that had been treated with the aforementioned pancreatropic hormone the author observed a considerable hyperemia and reasoned that, if the pancreatropic substance has such an effect it might be helpful in acute pancreatitis. For the last four years he has endeavored to obtain clinical experience with regard to the course of acute pancreatitis when the pancreatropic anterior pituitary hormone was employed as an adjuvant in the treatment. As soon as a case has been diagnosed as pancreatitis, the patient is subjected to a continuous drop infusion of physiologic solution of sodium chloride. One ampule of the substance (as fresh as possible) is introduced into the injection tube every eight hours during

the first day. From the second day on, it is given every six hours in the form of tablets, until the fasting blood sugar and the diastase values have been normalized or until improvement is noticeable. The author employed this auxiliary endocrine treatment in nine patients with acute pancreatitis. The results were encouraging. The blood sugar and diastase values decreased rapidly, and necessary interventions on the biliary system could be made early.

Lichen Urticatus of Exogenic Origin—Hamburger and Dietrich say that lichen urticatus, which is comparatively frequent in children, is generally ascribed to enterogenic causes. Eggs, milk, meat and various types of vegetables have been held responsible for it, but the authors show that bites of insects, particularly bedbugs, are often responsible for this type of skin disorders. They were able to demonstrate that among twenty-four children with lichen urticatus there were seventeen, or 70 per cent, who reacted to bites from bedbugs with the characteristic manifestations of lichen urticatus. Tests on sixty-six children without lichen urticatus revealed that only twenty-four or 36 per cent, were sensitive to bites from bedbugs. In many cases of lichen urticatus the causal significance of bedbugs could be definitely demonstrated by the fact that the children had a recurrence immediately after their return home. However, this was not the case when the bedbugs had been exterminated or the children were taken to a home that was free from bedbugs. The authors point out that it is an old established fact that there are persons who have a sensitivity to bites from bedbugs and they think that for this reason it is the more surprising that for the last two or three decades lichen urticatus has been so generally ascribed to nutritional factors. In experimental studies they were never able to elicit lichen urticatus by foods. They do not question that a typical urticaria may be of enterogenic origin, but they doubt that lichen urticatus originates in this manner. They emphasize that lichen urticatus in children is not of enterogenic but rather of exogenic origin. In the majority of cases it is probably caused by bites from bedbugs, but fleas or other insects may also be responsible.

Trombidiosis—Aretz says that trombidiosis is caused by mites of the genus *Trombicula*. The species *Trombicula autumnalis* seems to be the one which causes trombidiosis in Germany. Of the four developmental stages of the mite, only the larva lives above the ground and only the larva plays a part in the causation of trombidiosis. The larva is yellow to scarlet red, its length varies between 0.27 and 0.68 mm and its width between 0.19 and 0.49 mm. It has three pairs of legs, the mandibular pair having especially powerful claws. The larva becomes a parasite on birds, mammals or human subjects and with powerful mandibular claws penetrates the upper horny layer and introduces a salivary secretion, which transforms the upper layers in such a manner that they can serve as food. After sufficient food has been absorbed, the larva leaves the host. Experiments conducted by Fuhs and also by the author revealed that from three to four hours after the attack by the larva itching is felt and a small papule, from 1 to 2 mm in diameter, can be observed. Rubbing increases the itching. The papule becomes gradually larger and reaches its maximum after twenty-four hours. At the apex of the papule there may be a vesicle that is filled with clear fluid. After this vesicle dries up a tiny blood crust is visible. The extremely slow regression of the papule, which requires about fourteen days, begins on the second or third day. In regions where the skin is delicate the papules may become hemorrhagic. Itching persists until the papule has completely disappeared. Impairment of

the general condition exists only in severe cases. To be sure complications in the form of pyoderma may develop from scratching. Although severe forms of trombidiosis may develop in the tropics, the trombidiosis of the temperate zone has a favorable prognosis. The treatment is directed chiefly against the itching sensation. Application of soft (green) soap has been found helpful by Fuhs, von Mallinckrodt recommends a sulfur mixture and Hoffmann advises the use of ristin (ethylene glycol monobenzoate) and a 20 per cent perugen ointment. The author obtained satisfactory results with frequent baths and with a simple zinc mixture. He describes the groups of cases that came under his observation.

*Foundations of Dosage in Rotation Irradiation R du Mesnil de Roche mont—p 648

*Roentgen Therapy of Hyperthyroidism W von Wieser—p 712

Rotation Irradiation—Dessauer and his associates describe a method which makes it possible to apply greatly increased depth doses without increasing the doses that reach the skin and the covering layers. They admit that this method, namely rotation irradiation, has been suggested several times before but has never been systematically developed. The authors experimented with this rotation method for the last two years and gained the impression that the improvement obtained with it is so considerable that, as soon as the rotation chairs have become available, the method will be employed. If, for instance, a complete focal dose can be applied to a tumor of the sella turcica without the hair falling out and if in case of a complete Coutard irradiation there is hardly any reaction of the skin, this is such a relief for patient and physician that it will not be dispensed with. The essential factor of rotation irradiation is to apply the total dose to the disease focus through as large a body surface as possible. To accomplish this the body of the patient is placed so that it can be rotated and adjusted in such a manner that the focus of the disease is in the axis of rotation. If the body of the patient is slowly rotated, the rays reach the focus of the disease uninterruptedly (because the focus remains within the axis), but the surface layers move so that the cone of rays constantly reaches different layers. Another advantage of the rotation method is that it permits a closer approach to the object to be irradiated and thus makes possible a better utilization of the ray energy, so that the irradiation time can be greatly reduced. The authors further discuss dosimetry, the structure of the apparatus and the technique of the irradiation by rotation.

Dosage in Rotation Irradiation—Du Mesnil de Roche-mont discusses the geometric factors in rotation irradiation and the spatial distribution of the dosage that is obtainable under different practical conditions. He emphasizes that this knowledge is the basis of the practical application of the rotation method of irradiation regardless of the manner in which the rotation is accomplished, whether, as was suggested by Dessauer and done by this author, the patient is rotated around the stationary x-ray tube or the x-ray tube is turned around the patient as done by Flax. The distribution of the dose in the organism during rotation irradiation is determined by the difference in exposure time of the skin and of the focus at which the rays are directed. The author explains the computation of this difference in the time of exposure and clarifies the mathematical formulas used in this computation on a geometrical diagram. He also shows groups of curves that have been computed with these formulas and directs attention to the superior depth action and other advantages of rotation irradiation.

Roentgen Therapy of Hyperthyroidism—According to von Wieser roentgen therapy of hyperthyroidism is successful in only 60 to 70 per cent of the cases. He ascribes the considerable percentage of cases that fail to respond to roentgen treatment to the fact that, besides the primary form of hyper-

thyroidism, there are also secondary forms. There is one which develops as a sequel to cerebral disturbances in the sphere of the sympathetic nerve centers. In this connection he cites a case in which a previous lethargic encephalitis was the cause of a secondary hyperthyroidism. This case did not respond to irradiation of the thyroid, but as soon as the sympathetic centers in the brain were irradiated there was improvement. The author thinks that many failures of roentgen therapy in hyperthyroidism are due to the fact that the causes of the disorder have not been correctly recognized. He shows that a certain functional disturbance of the hypophysis resembles hyperthyroidism and that roentgen treatment of the thyroid fails in these cases. The fact that a number of such cases had been referred to him recently for irradiation of the thyroid induced him to discuss this problem. He says that, although these patients had an increased basal metabolism their obesity should have suggested the possibility of an erroneous diagnosis. In all these cases, determination of the specific dynamic value had been neglected. If this had been done, it would have been discovered that the specific dynamic value was not increased as in hyperthyroidism but was decreased. The author mentions two other forms of secondary hyperthyroidism that which results from infectious diseases, particularly tuberculosis, and that which is caused by excessive intake of thyroid extract or of iodine. The latter form usually improves when the intake of these substances is discontinued. In the concluding summary the author emphasizes once more that before roentgen treatment is begun in hyperthyroidism the cause of the disorder should be ascertained, for, if the process is one of the secondary forms, the treatment must be different than in the primary form. Roentgen irradiation of the thyroid is not effective in the secondary forms.

*Action of Crystalline Insulin on Blood Pressure, Respiration and Electrocardiogram as Well as Modification of These Effects by Metrazol A. Heinrich and Hildegard Sussner —p 208

Central Regulation of White Blood Picture—Behr reviews the literature on the central regulation of the white blood picture and then says that he observed that spinal puncture produces an increase in leukocytes. He believes that the degree and the type of changes in the white blood picture are to a certain extent dependent on the nature of the changes in the central nervous system. His observations were made in sixteen cases. The leukocytic blood picture was examined before, immediately after and twenty, forty and sixty minutes after the spinal puncture. The course of the leukocytic reaction and particularly the qualitative changes in the white blood picture permit a differentiation into three groups. To the first group belong four patients who had no pathologic changes in the central nervous system. The spinal puncture was made in order to verify the diagnosis. In these cases the spinal puncture produced only a slight increase in leukocytes. The second group, of four patients, had localized noninflammatory processes of the central nervous system. In this group the increase in leukocytes was more pronounced. It involved primarily the lymphocytes. The third group, of eight cases included those in which the changes in the central nervous system could be traced to inflammatory infectious processes, especially of a syphilitic nature, and in which the meninges were involved. In these cases the spinal puncture was followed by a strong increase in leukocytes. The qualitative analysis of the blood picture revealed a deviation in the myeloid direction. The author considers these observations interesting because the behavior of the leukocytic reaction after a spinal puncture permits some conclusions about the type of changes in the central nervous system. Inflammatory changes become manifest by a myeloid tendency in the leukocytic reaction, whereas purely degenerative processes are indicated by a noticeable

lymphatic tendency in the leukocytic reaction. On the other hand, these observations seem to be a further proof for an autonomic regulation of the white blood picture. However, it is still a question whether a separate center exists for this regulation.

Resistance to Insulin in Diabetes—A review of the literature on the resistance to insulin reveals no agreement about the nature of this phenomenon. The observations which Herbst made on the problem of resistance to insulin are based on sixteen cases. He emphasizes that the estimation of the efficacy of insulin cannot be based on the behavior of the blood sugar during fasting or on the total daily elimination of sugar. A patient can be regarded as resistant to insulin only if, after an injection of insulin, the blood sugar is reduced less than is generally the case under comparable conditions. Renal diabetes cannot be regarded as resistant to insulin. Its behavior toward insulin is just like that of the normal organism. The persistence of the glycosuria in spite of the reduction of the blood sugar is caused by the reduced renal threshold. The author further gives his attention to the extra-insular, epinephrinogenic diabetes. This type of diabetes, which is caused by a hyperfunction of the counterregulation, is generally not resistant to insulin. Only a great increase in the action of epinephrine may temporarily impair the function of insulin. Hepatogenic diabetes likewise cannot be regarded as resistant to insulin. Resistance to insulin in case of hyperglycemic diabetes due to insulin deficiency is caused by inactivating substances in the blood, by the influence of fever and especially by the effects of acidosis. From the clinical point of view it is possible to differentiate two types of resistance to insulin, those without and those with acidosis. In many cases an apparent resistance to insulin is simulated by an unsuitable distribution of the doses of insulin. In case of coma with resistance to insulin it is possible to break the resistance by the intravenous administration of alkali. This measure is effective even if the largest doses of insulin have proved ineffective.

Action of Crystalline Insulin on Blood Pressure and Electrocardiogram—Heinrich and Sussner state that the literature contains contradictory reports about the effects of insulin on blood pressure, respiration and the electrocardiogram. It has been shown that the various brands of insulin available on the market are not of a uniform nature and that some contain substances which act on the circulation. The authors suggest that some of the reported results might be due to these substances. They decided to study the action of crystalline insulin. Their tests were made on rabbits. They were able to show in these animal experiments that, following the injection of crystalline insulin, there is always a decrease in blood pressure, which is not a result of the hypoglycemia but of the crystalline insulin itself. Bradycardia and a lowering of the T wave was likewise observed in many instances. Once an arrhythmia was registered. All these manifestations were chiefly the result of the crystalline insulin. Only the repeatedly observed acceleration in the respiration must be regarded as a manifestation of hypoglycemia. The authors further investigated to what extent the changes that are elicited by crystalline insulin can be influenced by medicaments. They found that when metrazol was administered the decrease in blood pressure which lasted only seconds, was followed by an increase that persisted for minutes. Electrocardiographic tests frequently revealed that the T wave, which had become lower under the influence of crystalline insulin, showed a tendency to rise again. The effect of metrazol on the frequency varied in that acceleration or retardation occurred. The content of blood sugar was not influenced by metrazol. The authors discuss the mode of action of metrazol in the hypoglycemia that is elicited by crystalline insulin and point out that, since the described circulatory action of metrazol is of only limited duration, repeated injections of metrazol can be recommended for the prolongation of the hypoglycemia during insulin shock therapy. The combined application in one session of insulin shock therapy and metrazol shock therapy does not seem advisable at least as far as can be estimated from observations on animals. However, no objection can be made regarding the circulation to the alteration between insulin shock and metrazol shock at daily or longer intervals.

 *Relations Between Mumps and Later Nervous Disturbances Hermine Lichtenstern—p 130
 *Cervical Group of Facial Neuralgias J Wilder—p 136

New Therapy of Narcolepsy—Fessler points out that for symptomatic narcolepsy that is not caused by tumors, syphilis or trauma there is as yet no satisfactory treatment. Nitschke's observation that hibernation of hedgehogs could be prevented by the administration of irradiated ergosterol induced Fessler to try it for patients with narcolepsy. He reports the histories of two cases in which he resorted to this medication. In the first case no treatment of any kind was given during the first eight days and there was no change in the narcolepsy. Thus the objection is answered that change in surroundings alone will produce a considerable improvement in narcolepsy. After the eighth day the patient was given ten drops twice daily. During the first two days of this medication there was no change, but during the subsequent nine days the patient was entirely free from attacks, although there still were times when he felt tired. On the twelfth, sixteenth and twenty-third days after the onset of the treatment, one attack each occurred. After the patient's return to the home surroundings the attacks of narcolepsy recurred when no irradiated ergosterol was taken, but they became much less frequent when it was taken again. For a more objective estimation of the effect of irradiated ergosterol, complete abstinence from alcohol was enforced for weeks. It was found that this reduced the incidence of the attacks of narcolepsy, but only when irradiated ergosterol was given at the same time did the attacks stop completely. In order to avoid excessive dosage and its possible dangers, the calcium content of the serum was kept under constant supervision; it remained approximately normal. In the second case the medication with ergosterol was not quite as effective as in the first. The second patient was much older than the first one and the treatment was begun with smaller doses. When complete abstinence from alcohol was enforced and comparatively large doses of irradiated ergosterol were given, the attacks of narcolepsy ceased.

Mumps and Later Nervous Disturbances—Lichtenstern reviews the literature on the later sequels of mumps and then reports her observations on 664 women and 520 men who were admitted to a hospital for nervous diseases. Of the women 105 and of the men forty seven had supposedly had mumps. It was the author's aim to determine whether there are diseases which are especially frequent in patients who have had mumps. She realizes that the number of cases of mumps is too small to allow definite conclusions, but she nevertheless investigated the possibility of a correlation between mumps and later disorders. Summarizing her observations she says that in the patients who had had mumps she noted a high incidence of hepatic disorders, diseases of the gallbladder, infectious diseases, appendicitides, articular disturbances and neurasthenic syndromes. A relative predominance of chronic cerebral or meningeal symptoms, particularly of headache, was not observed. Endocrine disturbances were likewise not especially frequent. In the men who had had mumps, sexual disturbances and arteriosclerosis were even less frequent than could have been expected on the basis of averages. The relatively higher incidence in infectious diseases was to be expected if it is considered that persons who are more susceptible to infections are also more subject to mumps. In view of the presumably different etiology of arthritides, their comparatively high incidence is not readily understandable. Discussing the great frequency of cholecystopathies and of hepatic disorders, the author says that only hypothetical considerations are possible so far. She suggests that the occurrence of a primary impairment of the pancreas during epidemic parotitis might result in a secondary impairment of the liver.

 *Tuberculosis of the Tonsils S I Libin and M V Travushkina—p 61
 *Erythema Nodosum in Allergic Reaction in Tuberculosis N A Tsukerman and P T Rybak—p 75

Tuberculosis of the Tonsils—Libin and Travushkina state that, in the belief of most authors, the tonsils of patients with pulmonary tuberculosis become secondarily infected through the sputum. Primary tuberculous infection of the tonsils is believed to occur rarely. The authors found on necropsy of 3,509 cases of pulmonary tuberculosis 605 cases of tuberculosis of the tonsils among 936 cases of tuberculous lesions involving the buccal cavity. The authors made a microscopic study of the tonsils in fifty necropsies in which death had resulted from pulmonary tuberculosis. A clinical diagnosis of tuberculous infection of the tonsils was made in two cases in this group. Anatomic diagnosis was made in seventeen cases. On microscopic observation, a diagnosis of tuberculous infection was made in twenty-seven cases in the absence of any macroscopic lesion. The difficulty in making a clinical diagnosis of tuberculosis of the tonsils is due to the fact that the process develops from the interior of the organ and spreads toward the periphery rather than in the reverse order. This fact likewise suggests that the infection takes place by way of the blood supply rather than by the sputum containing tubercle bacilli. The hematogenous origin of the infection is further supported by the fact that the microscopic evidence of tuberculosis was bilateral in all their cases but one. The authors conclude that tuberculous infection of the tonsils in patients with pulmonary tuberculosis is a frequent occurrence, even though it is not recognized with great frequency clinically or at necropsy. They believe that tonsillar tuberculosis is of considerable clinical importance so far as it contributes to the general intoxication of the organism and gives rise to metastases. The microscopic form is predominantly that of productive inflammation with but few demonstrable tubercle bacilli or with none. The exudative form with ulcerative lesions, considerable necrosis and numerous tubercle bacilli was encountered but rarely. The question of the mode of infection cannot be determined from microscopic studies. The hematogenous route probably plays the most important part in the tuberculous infection of the tonsils.

Erythema Nodosum as Allergic Reaction in Tuberculosis—According to Tsukerman and Rybak, a number of observers pointed out that children suffering from erythema nodosum react to tuberculin with great intensity. Thus the sensitivity to tuberculin in such children was in many instances increased to the point of reacting to dilutions of 1 1,000,000, whereas reactions to dilutions of 1 100,000 or 1 1,000 is the rule. The sensitivity to tuberculin is moderate or negative before the appearance of the eruption. With the rise of the temperature and the appearance of the eruption it becomes greatly heightened. The eruption thus coincides with hyperallergy. At the same time pathologic increase of roentgenologic shadows at the root of the lung become demonstrable. The authors emphasize that erythema nodosum is not to be considered a tuberculous lesion. From an anatomic point it is not a tuberculous process. While children with erythema nodosum react to nonspecific bodies as well, such reactivity is transient, whereas the reactivity to tuberculin persists. In fourteen children recently recovered from erythema nodosum the authors found a positive reaction to the tuberculin. In twelve it was intense, exhibiting vesicles on the surface of the papules in some. A diagnosis of tuberculous infection was made in all of the group. Of these eight had tuberculous bronchoadenitis, two had pulmonary tuberculosis, two developed pleurisy with effusion, one tuberculous meningitis and one an allergic state. Roentgenologic examination showed tuberculous infection in all. Contact with open cases of pulmonary tuberculosis was found to have existed in seven. The authors conclude that every case of erythema nodosum in a child must be regarded as one in the acute stage of tuberculous allergy and should be observed as such by the tuberculosis dispensary.

EPIDEMIC DIARRHEA OF THE NEWBORN

WILLIAM H. BEST, M.D.
Deputy Commissioner, Department of Health
NEW YORK

In July 1934 the attention of the department of health was called to some sort of epidemic among the newborn babies in one of the New York City hospitals. This information was given by the father of one of the babies who had died and was to the effect that many of the babies at the hospital were ill and many dying. We investigated this complaint and to our dismay found an epidemic of enteritis of a devastating nature in progress among the newborn babies. Before it had ended, seventy-two, or 18 per cent of the babies in the nursery had been involved, of whom thirty-two died, a mortality of 45 per cent. Postmortem, pathologic and bacteriologic examinations gave no clue as to what we were dealing with.

Since the discovery of this outbreak of diarrhea among the newborn, although we have become quite familiar with the clinical syndrome, its etiology and its mode of transmission still remain in the realm of speculation. Was it possible that this condition was occurring in other institutions from time to time without recognition? Was it possible that similar outbreaks had occurred in other parts of the country? There was, indeed, a paucity of reports in the literature. In fact, even up to the present there have been, so far as we are able to ascertain, only about eight references to a condition similar to this one. In an effort to answer this question, the Sanitary Code of the City of New York was amended, making diarrhea of the newborn in lying-in institutions reportable, and death certificates from institutions were checked daily. Whenever there seemed to be a disproportion in the number of deaths of infants under 4 weeks of age to that which might be normally expected we made inquiry, irrespective of what was given on the certificate as the cause of death. Investigations, as a result of these procedures, have uncovered a trail which has led us a long way and, while much remains to be revealed, we believe that we are dealing with an acute communicable disease of the newborn.

From July 1934 to the end of December 1937, we have studied twenty-seven outbreaks, comprising nineteen different hospitals. Fourteen hospitals experienced only one outbreak, three hospitals had two, one hospital three and one hospital as many as four outbreaks during this period. The time interval in the hospitals with multiple outbreaks would not indicate any relationship

between the first and subsequent ones. From July 1934 to December 1934 there was one outbreak with seventy-two cases and thirty-two deaths, during 1935 seven outbreaks with 205 cases and ninety-six deaths, during 1936 ten outbreaks with 245 cases and 121 deaths, during 1937 nine outbreaks with 228 cases and 107 deaths. There were nine outbreaks which had their beginning in the winter months (December 21 to March 21), four outbreaks in the spring months (March 22 to June 21), nine outbreaks in the summer months (June 22 to September 21) and five outbreaks in the fall months (September 22 to December 21). This distribution would not indicate a seasonal or climatic predilection. In these twenty-seven outbreaks we have followed the postnatal course of 5,082 live born babies. Of this total, 750 developed the disorder, a morbidity rate of 14.7 per cent. Of the 750 babies attacked, 356 died making a mortality rate of 7 per cent and case fatality rate of 47.5 per cent.

SYMPTOMATOLOGY

The infant appears to be healthy and thriving. Suddenly it is noted that the child is unusually drowsy and if awakened gives a short, feeble cry. The temperature may be slightly elevated, from 99 to 100 F. Coincidentally or within a few hours, loose, watery, yellowish stools develop, less frequently yellowish brown or greenish, with however no mucus, blood or pus. Occasionally vomiting is present. Distention is also a frequent symptom. Watery stools of increasing frequency occur and weight loss amounting to as much as a pound within twenty-four hours may be noted. The general appearance of the baby changes from that of a previously healthy nursing to that of a markedly dehydrated and marantic infant in shock. In severe cases death may occur in a day or two, in the less severe cases the disease may run a course of from five to seven days, finally terminating in death or going on to recovery in about 50 per cent of the cases. A terminal bronchopneumonia has been noted in some of the fatal cases, several have been complicated by an otitis media which developed late in the course of the disease.

In brief, then, there is a symptom complex of a severe intestinal toxemia with acute onset, accompanied by drowsiness, watery yellowish stools, abdominal distention, marked dehydration, rapid loss of weight and shock.

EPIDEMIOLOGY

This disorder seems definitely limited to the newborn period, the susceptible age being up to 4 weeks. Contacts discharged home from the affected nurseries and later becoming ill were returned to the hospital and admitted to the regular pediatric ward. At no time did the condition spread to older children in the ward. In no instances have the adult attendants in the affected

nurseries become infected. Sick infants discharged home as well as babies becoming ill at home after discharge have in no instance communicated the infection to older members of the family. After the first case, the spread in the nursery is rapid, usually involving infants in adjacent bassinets. This fact and the fact that infants have come down with the disorder in as short a time as one or two days after having been placed in a nursery where cases had developed, would seem to indicate as a rule a very short incubation period. However, there was one instance in which the infant was taken ill twenty days after discharge from the hospital. The majority of the cases developed between two to six days after the presumed exposure. It not infrequently happened that there was a cessation of new cases for several days, even for a week, only to start up afresh. During this remission period new babies were admitted to the nursery, thereby providing further fuel for the perpetuation of the epidemic. The outbreaks were never fully controlled until the maternity service involved was completely closed to new admissions and, in the course of time, the babies discharged and the obstetric and nursery quarters renovated. Sex and race do not appear to be a factor. Since, in many hospitals, supplementary feedings and fluids are given, at least during the first week, all the pathways for the introduction of infection are open alike to the breast fed as well as the artificially fed baby. This, undoubtedly, accounts for the fact that there was no marked difference in the incidence among breast fed and artificially fed babies.

BACTERIOLOGY

Bacteriologic investigation in our laboratory has thus far failed to reveal a common etiologic agent. Stools from cases and bowel contents taken post mortem disclosed a variety of organisms, namely, *B. coli*, atypical *B. coli*, Flexner bacillus and enterococcus (streptococcus). To complicate the picture further, in outbreaks outside New York City other organisms have been reported. Jampolis and his associates reported a *B. mucosus capsulatus* and a nonhemolytic streptococcus from the Michael Reese Hospital, Chicago, in 1930. At Johns Hopkins Hospital, Schwentker, in a personal communication, reported a *B. dispar* in 1935, and Park and Christie a non-lactose fermenting *B. coli* in 1936. A monilium was reported by Durand from the Providence Hospital at Seattle in 1935. In routine cultures of nasal and pharyngeal secretions and of stools of sick babies and mothers and adult maternity service personnel, we have failed to isolate a common organism among the sick babies or an organism common to both the adults and the sick infants. Virus studies made at our laboratory and at the Rockefeller Institute have thus far failed to throw any light on the nature of the morbid agent. May it not be an organism or even a variety of organisms nonpathogenic for older individuals but pathogenic when introduced into the intestinal tract of the newborn? This is put merely as a question.

PATHOLOGY

It is surprising that such a severe intestinal toxemia can produce so little pathologic change. While some congestion of the superficial vessels in the bowel, congestion of Peyer's patches and occasional hemorrhagic areas were noted, no constant characteristic pathologic condition, either macroscopic or microscopic could be established. Otitis media, parenchymatous degeneration

of the liver and kidneys, bronchopneumonia and congestion of the dural and meningeal vessels were occasionally found.

COMMENT

To the health officer, these institutional epidemics present a serious problem, since they affect an age group in which the mortality rate has shown the least reduction. The reduction in the infant mortality rate during the past quarter of a century in New York City is about 61 per cent. However, the reduction in deaths under 1 month of age during the same period has been only about 28 per cent. The infant mortality rate for diarrheal conditions from 1 month to 1 year a quarter of a century ago was 31 per thousand live births, whereas last year it was 3.6, a reduction of 90 per cent. The infant mortality rate for diarrheal conditions under 1 month for the same period was 2.5 per thousand live births, whereas last year it was 1.9, a reduction of only 24 per cent. As a matter of fact, in the past ten years an actual increase is shown. It is apparent that, if further progress is to be made in the reduction of infant mortality, measures to control or prevent these epidemics must be instituted. With the uncontrolled expansion of lying-in institutions and the mass collective care of the newborn in nurseries, with the great variety of institutions—municipal, voluntary and private, large and small—and added to this a lack of exact knowledge of the etiology and mode of transmission, the development of control measures becomes a complicated problem.

CONTROL MEASURES

First, as to the control of the outbreak in an institution. We have learned from experience that temporizing in the hope that the disorder will abate is of no value. Measures and procedures customarily employed in communicable diseases, namely, the immediate isolation of suspected cases, the closing of the maternity and newborn services involved until all the infants have been discharged and thorough cleansing and renovation of the nursery, constitute the speediest way to control an outbreak.

Second, and more important, is to prevent the outbreaks from occurring. This necessitates, in many hospitals, a radical change in the physical setup and the techniques in the obstetric and newborn services.

The basic principle involved is that everything coming in contact with the baby's mouth or nose should be in a surgically aseptic condition. Therefore the obstetric and nursing techniques must be set up to this end. With this in mind and after numerous conferences with leading obstetricians, pediatricians, representatives of the county medical societies, the Academy of Medicine and various hospital medical and nursing groups, regulations governing lying-in institutions and nurseries for the newborn were established.

THE REGULATIONS

Lying-in Institutions and Newborn Nurseries Regulated—No person, organization or corporation shall conduct, maintain or operate a lying-in institution or a newborn nursery otherwise than in accordance with the regulations of the Board of Health.

Lying-in Institutions and Newborn Nurseries Defined—The term lying-in institution as used herein shall be deemed to mean any hospital, institution or place, excepting private homes in which pregnant women are cared for and delivered of babies. The term newborn nurseries as used herein shall be deemed to mean any room, rooms or ward in such hospitals, institutions or places, excepting private homes, in which newborn babies are cared for or treated.

REGULATION 1 Maternity and Delivery Room Units—(a) There shall be adequate isolation quarters for ill or infected mothers in all lying-in institutions. A mother shall be deemed infected if (1) she is a carrier or suspected carrier of, or affected with, a communicable or suspected communicable disease or condition, or (2) if she nurses an ill or infected baby, or (3) if she is not delivered in a lying-in institution in which she is afterward cared for. Ill or infected mothers shall be immediately isolated.

(b) There shall be provided and maintained a separate labor and delivery room unit with separate equipment for the delivery of normal or clean operative obstetric cases and another such equipped unit for the delivery of ill or infected mothers. If the latter unit with separate equipment is not provided and the delivery of an ill or infected mother is carried on in the unit used for normal or clean operative obstetric cases, the same shall be immediately and thoroughly cleansed, closed for twenty-four hours and the equipment resterilized.

(c) The maternity ward or unit shall be maintained separate and apart from any medical or surgical service not intimately concerned with the delivery or puerperal period.

(d) Gynecologic operative procedures shall be prohibited on maternity services, except such as are intimately concerned with the delivery or the puerperal period.

(e) Equipment of delivery rooms shall be limited to instruments and supplies necessary for immediate use. All other equipment and supplies shall be kept in outside supply rooms.

(f) All labor and delivery room units shall be equipped with proper apparatus and supplies for safeguarding the lives of the newborn infants and the mothers.

REGULATION 2 Newborn Nurseries—(a) Every lying-in institution shall maintain in good order at least two separate regular nurseries, one for the care of normal newborn infants and another for the care of premature and immature infants. These nurseries shall be an integral part of the maternity service.

(b) Separate isolation quarters shall be maintained at all times for the isolation of ill or infected babies. A baby shall be deemed infected (1) if a carrier or suspected carrier of, or affected with, a communicable or suspected communicable disease or condition, or (2) if delivered of an ill or infected mother, or (3) if delivered outside the lying-in institution. Such ill or infected baby shall be immediately isolated. The isolation quarters shall be in a division of the maternity service separated from the main nurseries.

(c) All nurseries, isolation quarters and the halls adjacent thereto shall be adequately and properly lighted, ventilated and heated, protected from noise and odors and kept free from insects and vermin. These rooms and hallways shall at all times be maintained in good repair and in a clean and sanitary condition. Walls and ceilings of these rooms and hallways shall be so constructed as to be easily cleaned and washed.

(d) The spacing between adjoining bassinets in all nurseries and isolation quarters shall be maintained at a minimal distance of six inches on all sides. Where a carrier system is used the bassinets shall also be so arranged that the infant is at least six inches below the upper surface of the carrier. The suspension of bassinets on double tier racks shall be prohibited.

(e) Where common dressing, bathing or diapering tables are used, these shall be draped with sterile linens or suitable clean paper sheeting for each baby immediately before use.

(f) The weighing scale shall be draped with sterile linens or suitable clean paper sheeting for the weighing of each baby immediately before use.

(g) Individual sterilized rectal thermometers shall be provided for each baby.

(h) Common or group baby carriers for taking newborn babies for feeding to their mothers shall be prohibited, unless they are provided with bassinets arranged in accordance with paragraph d of this regulation.

(i) Each and every nursery shall be provided with running hot and cold water. The isolation quarters, if newly constructed or altered after Jan. 1 1938, shall be provided with running hot and cold water.

(j) Each and every nursery and the isolation quarters of such nursery shall be provided with proper receptacles for the temporary disposal of soiled linen, diapers and waste. Such soiled articles shall be removed immediately or within a reasonable time from the nursery or isolation quarters.

(l) All bottles used for feeding babies shall be cleaned and sterilized in the nursery quarters before return to the formula room or suite.

(l) Anything coming in contact with or introduced within the baby's nose or mouth must be made sterile and handled only by a person who has scrubbed and disinfected his or her hands and put on sterile rubber gloves. All tongue depressors, applicators, ear specula and other examining instruments shall be standard nursery equipment and separate sets shall be maintained for each nursery and for each isolation quarter, and shall be sterilized before use for each baby. The bowls of stethoscopes shall be cleaned with a proper solution of alcohol, cresol or other disinfectant before use for each baby.

(m) All gauze, cotton, swabs or other materials intended for use in the care of the baby shall be sterilized and kept or stored in sterile containers.

(n) Equipment of the nursery shall be limited only to furnishings and supplies necessary for the immediate care of the infants.

(o) Dry dusting or sweeping shall be prohibited in all the nurseries and adjoining hallways.

REGULATION 3 The Newborn Nursery Laundry—All nursery linens, including diapers and articles of infants' clothing, shall be kept separate from linens of other parts of the hospital and when soiled shall be washed and sterilized separately from the linens of other parts of the hospital, in a separate laundry or in the same laundry at definite periods set aside for the laundering of these nursery linens only. Such sterilization shall consist of boiling the linens in water for fifteen minutes and of thorough rinsing in clean water, or of another approved method of sterilization.

REGULATION 4 Formula Room or Suite—(a) A formula room or suite shall be maintained in all lying-in institutions, specifically for the purpose, completely separated from any diet kitchen, pantry, scullery, or other place of food storage or preparation.

(b) The formula room or suite shall be provided with adequate refrigeration facilities for formulas and milk supplies, and with adequate sterilization facilities for the sterilization of bottles, nipples, bottle caps and other formula preparation utensils.

(c) Any nurse or dietitian preparing or assisting in the formula room or suite in the preparation of formulas for babies of the newborn nurseries shall, before beginning such duties, remove her outer garments, put on a sterile cap and mask, scrub hands and put on sterile gloves and a sterile gown. An aseptic technic such as is carried out in operative procedure shall be maintained at all times.

(d) All bottles, nipples, bottle caps and other formula preparation utensils shall be adequately sterilized in the formula room or suite before use in preparing or bottling formulas. Nipples may be sterilized in the nurseries immediately before use.

(e) Each baby shall have its individual set of properly labeled bottles sufficient for a day's feeding. The storing of formula feedings in bulk is prohibited.

REGULATION 5 Accessory Rooms—In lying-in institutions where ritual circumcision is done, a separate room shall be maintained for this purpose which room shall be completely divided by a glass partition of at least six feet in height. One side of this room shall be used for the circumcision procedure and the other side for witnesses. All persons concerned with the ritual circumcision shall follow the aseptic technic outlined in regulation 13a and all procedures connected therewith shall conform to this technic.

REGULATION 6 Sanitary Equipment—All nurseries, isolation quarters, formula rooms, examining rooms, labor and delivery rooms and maternity rooms or wards shall each have adequate facilities for the scrubbing of hands, suitable disinfectant solu-

tion, and receptacles for the efficient temporary disposal of soiled linens and waste. All plumbing, plumbing fixtures, sterilizers and other similar equipment shall be so constructed, installed and maintained as to prevent cross connections or other sanitary hazards.

REGULATION 7 The Nursing Staff—(a) A separate nursing staff under the supervision of a registered graduate nurse shall be maintained, both day and night, in the nurseries and isolation quarters concerned with the care of the newborn. Not more than one unit of eight babies shall be under the care of any one individual nurse at any time during the day or night.

(b) Nurses assigned to formula room duty shall be prohibited from doing any type of duty at any time which may bring them in contact with a septic or infected patient in any part of the hospital.

(c) Nurses assigned to the nurseries shall wash their hands thoroughly with soap and hot water immediately after changing or diapering each baby. If at any time during the feeding of any baby it becomes necessary to handle or change the nipple of a feeding bottle, the nurse shall scrub her hands thoroughly with soap and hot water and put on sterile rubber gloves, unless the handling or changing of the nipple is carried out by means of sterile forceps in such a way that the hands of the nurse will not come in contact with the nipple.

(d) All nurses assigned to the isolation quarters shall be prohibited from entering the regular or the premature nurseries.

(e) Private nurses may be admitted to the nurseries of private pavilions, provided they comply with all the prescribed regulations as outlined in regulation 13a.

(f) No person shall enter the nurseries or the isolation quarters except those immediately concerned with the care of the newborn.

REGULATION 8 The Medical Staff—The medical board or other governing body of such hospital or institution shall designate whether the newborn nurseries are under the supervision of the obstetric or pediatric service. Such designation shall be in writing and kept on file in the office of the superintendent and be available for inspection at any time by a representative of the Department of Health.

REGULATION 9 Maternity and Newborn Service Case History Records—Complete and detailed case history records shall be kept of the progress of all maternity patients and their babies and be available for inspection at any time by a representative of the Department of Health.

REGULATION 10 Examination of Maternity and Newborn Service Personnel—(a) All personnel on duty on the maternity or newborn services, when these regulations go into effect, shall be examined by a physician designated by the hospital management and be certified by him as showing no evidence of communicable disease or a respiratory, urinary or fecal carrier state.

(b) All new personnel shall be similarly examined prior to assignment to the maternity or newborn service.

(c) All personnel on duty on the maternity or newborn services shall report immediately to a physician designated by the hospital management any indisposition however slight such individuals and all individuals absent from duty because of any illness whatever shall be excluded from the maternity and newborn services until examined by the physician designated for the purpose and certified by him in writing to the superintendent as not suffering from any condition that may endanger the health of the mothers or babies. All such certifications shall be kept on file in the office of the superintendent and shall at all times be open to inspection by a representative of the Department of Health.

REGULATION 11 Examination of Maternity Patients—All maternity patients shall have a complete history taken, a thorough physical examination, and inquiry made on admission as to any infection. Any history or examination that reveals a communicable or suspected communicable condition or disease or a respiratory, urinary or fecal carrier state shall be sufficient cause to have such patients isolated.

REGULATION 12 The Care of the Newborn Baby—The newborn infant shall be examined for hemorrhage, injuries, defects or signs of infection immediately on delivery and be further observed daily. If any infection is found or suspected the baby

shall be isolated immediately. All babies shall be reexamined at the time of discharge.

REGULATION 13 The Aseptic Nursery, Maternity Ward and Delivery Room and Feeding Technic—(a) **Nursery Technic**—All doctors, nurses and other hospital personnel in attendance on babies in any of the newborn nurseries or isolation quarters shall remove coats or other outer clothing, bare their arms to the elbows, wash their hands and arms thoroughly with soap and hot water and put on clean caps, gowns and masks. In addition they shall wash their hands with soap and hot water and immerse them in a suitable disinfectant solution before the handling of each baby. Babies shall be handled as little as possible, and in strict accordance with an aseptic procedure as close to that of an aseptic operative procedure as is possible.

(b) **Maternity Ward Technic**—All doctors, nurses and other hospital personnel before attendance on maternity patients in other than individual private rooms shall remove coats or other outer clothing and put on clean caps, gowns and masks. No visitors shall be permitted beyond the foot of the bed of the patient, nor shall outer clothing be permitted to be placed on the beds of patients.

(c) **Delivery Room Technic**—This shall be in accordance with recognized and approved surgical operative technic.

(d) **Feeding Technic**—At feeding times the mother shall be provided with a clean mask prior to receiving her baby for feeding. The mother's breasts shall be thoroughly cleansed before each nursing.

REGULATION 14 Visitors and Visiting Hours—(a) Visiting hours to maternity services shall be set at such a time as not to coincide with the hours when the newborn infants are in the maternity ward or rooms for nursing by their mothers. There shall be a minimum of visiting permitted on all maternity services.

(b) Visitors or individuals not connected with the direct care of the babies shall be prohibited from entering the newborn nurseries at any time.

(c) Children under 14 years of age shall be prohibited from admittance to any maternity ward at any time.

REGULATION 15 Copy of Regulations to be Kept Readily Available—A copy of these regulations shall be kept on the maternity service of all lying-in institutions for the information and guidance of all personnel connected with such service.

It is probable that, with further experience, these regulations may be amended by adding others or deleting some that may be found unnecessary. However, we believe that these regulations are basically sound and indicate the fundamental principles on which a well regulated maternity service should be conducted to the end that not only epidemic diarrhea of the newborn will be controlled but that neonatal morbidity and mortality from other causes may also be reduced.

The Vegetative Nervous System—This portion of the nervous system has been termed by various workers sympathetic, autonomic, vegetative or involuntary. Since it is not completely involuntary or autonomic and cannot be separated from somatic functions, we shall use the terms sympathetic or vegetative nervous system. We shall apply to the thoracolumbar portion of the vegetative nerves the name orthosympathetic, while terming the bulbosacral outflow parasympathetic. The nerves belonging to the vegetative nervous system innervate unstriated (smooth) musculature in general, which includes the blood vessel walls, heart, lungs, bladder, glandular structures and the viscera. Generally speaking the nerves innervate structures which are concerned with internal activities of the body, those necessary to the continuance of life and those which must be adjusted for, or as a result of external changes. This nervous organization is concerned with the internal matrix (vital functions) within which the processes of life are based. The fine coordination of the various component parts of the vital machine, their modification to meet sudden stresses and their adaptation to environmental factors are in general vegetative functions.—Grinker, Roy, R. Neurology, ed 2, Springfield Ill. Charles C. Thomas 1937.

LAENNEC'S CIRRHOSIS

REPORT OF 217 CASES

NEWTON EVANS, MD

LOS ANGELES

AND

P A GRAY, MD

SANTA BARBARA, CALIF

The clinical impression has long been current that the excessive consumption of alcoholic beverages is conducive to the development of Laennec's type of cirrhosis of the liver. This impression has persisted in spite of the general failure to reproduce this lesion experimentally by feeding alcohol to laboratory animals. Mallory¹ has suggested that minute amounts of phosphorus alloyed with iron which may be present as contaminating traces in liquors may be the real etiologic factor. Von Gerlach² found that the copper content of the liver of patients with cirrhosis was elevated and suggested that this mineral in conjunction with alcohol may be significant. Moon³ recently reviewed the literature dealing with the experimental attempts to produce cirrhosis artificially and decided that no single factor can be responsible, that several factors must operate simultaneously and that, of these, nicotine, manganese and phenylhydrazine are probably significant. Boles and Clark⁴ have also rejected the alcoholic theory, on the basis of their autopsy statistics.

The autopsy records of typical cases of Laennec's cirrhosis (portal, nodular or atrophic) from the Los Angeles County Hospital have been examined in an effort to gain further insight into the etiology of this

(chart 1). The beginning of this rise coincided with the repeal of the national prohibition law. The incidence for the period since repeal is three times that observed before (table 1).

As has been observed in other series, the sex incidence of these 217 cases shows a preponderance of males over females (25:1, table 2). The ratio of males to females is slightly higher (26:1) in the period from 1933 to 1937 than in the earlier one (195:1). Most of the cirrhosis has occurred from the fourth to the eighth decade, inclusive (chart 2). Although the peak of incidence for the group as a

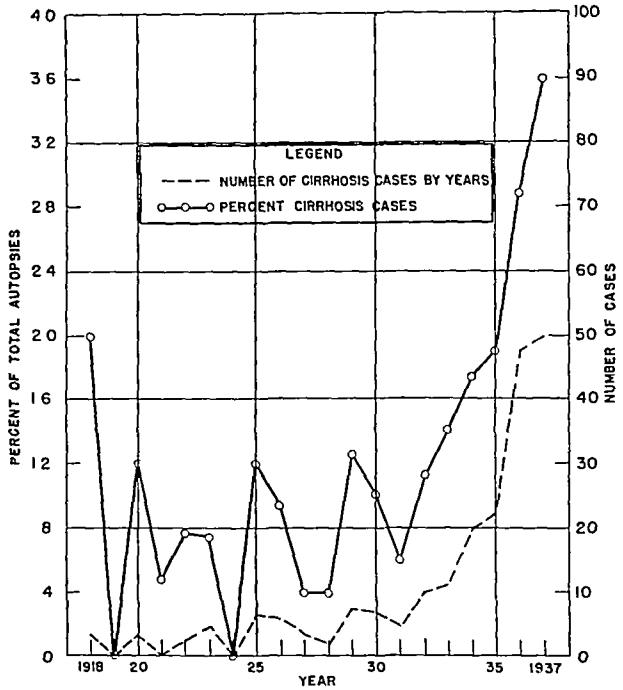

Chart 1.—The rising incidence of cirrhosis. The data for 1937 were estimated for twelve months on the basis of those collected in the first four months.

TABLE 1—Incidence of Cirrhosis

| Years | Number of Autopsies | Number of Cases of Cirrhosis | Percentage of Cirrhosis |
|-----------------------|---------------------|------------------------------|-------------------------|
| 1918-1937 (inclusive) | 9 527 | 62 | 0.65 |
| 1933-1937 (May 1) | 8 247 | 155 | 1.84 |
| Total | 17 874 | 217 | 1.21 |

TABLE 2—Sex Incidence

| | Males | Females | Total |
|-----------|-------------|------------|-------|
| 1918-1932 | 41 | 21 | 62 |
| 1933-1937 | 114 | 41 | 155 |
| | 1.5 (71.4%) | 62 (28.6%) | 217 |

interesting lesion. Records on 17,874 autopsies performed from Jan 1, 1918, to May 1, 1937, are available. In these, 217 cases of Laennec's cirrhosis were observed. This represents a gross incidence of 1.2 per cent, which is lower than the figures available to us (Mallory¹ 3 per cent, Boles² 6 per cent and Ophuls³ 2.2 per cent). When arranged chronologically, these cases of cirrhosis show a definitely rising incidence

whole falls in the sixth decade, that of the females occurs a decade earlier than that of the males.

Since we have been concerned chiefly with the so-called alcoholic type of cirrhosis, cases of hypertrophic, biliary and syphilitic cirrhosis have been excluded from this study. The criteria used in classification have been as follows:

The liver usually appears shrunken, deformed and covered with yellowish brown or orange colored projections. The tissue between the projections is gray and firm. The liver cuts with increased resistance, the cut surface shows distortion of the normal lobular pattern, projections of varying size and scarring.

The principal factor contributing to death in this series was lobular pneumonia or bronchopneumonia, of which 33.6 per cent of the patients died (table 3). It was difficult to determine in many instances whether bronchopneumonia was the actual or only a contributing cause of death. For the purposes of this report a patient dying with bronchopneumonia was assumed to have died of it. Frequently this lesion was hemorrhagic and of the aspiration type.

Next in order of frequency as an immediate cause of death was hemorrhage from the gastro-intestinal tract (20 per cent). Thirty patients (13.9 per cent) had ruptured esophageal varices with fatal hemorrhage.

One half (fifteen) of these did not have ascites. In this group without ascites a correct clinical diagnosis was made ante mortem only twice. In the fifteen cases of esophageal hemorrhage with ascites a correct diagnosis was made thirteen times.

The presence of ascites was the principal factor in the whole group of cases conducive to a correct ante-

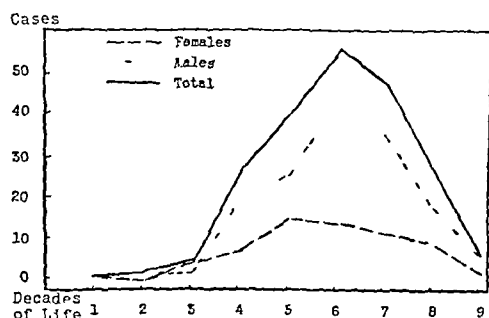

Chart 2—Incidence of cirrhosis according to age and sex

mortem diagnosis. In all, there were 131 cases of ascites, and a correct diagnosis was made in 56.5 per cent. On the other hand, in the eighty-six cases without ascites a correct diagnosis was made in only 15.1 per cent. In the total 217 cases of cirrhosis a correct ante-mortem diagnosis was made in only 41.5 per cent.

The third or next most prominent group consisted of cases of cirrhosis without concomitant complications. Death in these cases was presumably due to changes within the liver itself, or "liver insufficiency." Twenty-five (11.5 per cent) such instances were noted. The livers were as a rule of less than average size. Their average weight equaled 1,364 Gm., only six (2.4 per cent) were above 1,500 Gm. Twenty-two (8.8 per cent) of the patients showed ascites, and eleven (4.4 per cent) were jaundiced.

A change in the gross pathologic characteristics of the livers of the patients with cirrhosis occurred in the past few years. In the period from 1918 to 1932 the livers ranged in weight from 480 to 2,700 Gm. (One 2 year old child had a liver weighing 110 Gm.) Of the fifty-eight livers in this group whose weight was recorded, seventeen (29.3 per cent) weighed 1,500

TABLE 3—Cause of Death in Cases of Cirrhosis

| | Cases |
|------------------------------|-------|
| Pneumonia | 73 |
| Lobular | 8 |
| Lobar | 43 |
| Gastro-intestinal hemorrhage | 26 |
| Liver insufficiency | 10 |
| Peritonitis | 9 |
| Cardiac failure | 6 |
| Malignant process | 6 |
| Tuberculosis | 5 |
| Cerebral softening | 3 |
| Portal thrombosis | 2 |
| Mastoiditis | 24 |
| Miscellaneous | 217 |

Gm. or more. In the later period, 1933 to 1937, the average weight of the liver tended to be greater. The livers ranged from 675 to 3,800 Gm. Of the 153 livers in this group, eighty-three (54.2 per cent) weighed 1,500 Gm. or more (table 4). The increased size and weight of the livers in the second group was in most instances due to the presence of fatty change.

This increased incidence of fatty change in cirrhotic livers somewhat parallels that of fatty livers seen in this laboratory in patients with chronic alcoholism

who died without clinical evidence of Laënnec's cirrhosis. Chart 3 shows the percentage of such livers to the total autopsies for the past four and a half years. These cases represent persons whose condition was diagnosed clinically as chronic addiction to the excessive use of alcohol and in whom no other lesion was found at autopsy to explain the fatty degeneration of the liver.

Sixty-four (29.5 per cent) of the 217 patients with cirrhosis were jaundiced. Of these, seven (10.9 per

cent) showed acute hepatic necrosis complicating the atrophic cirrhosis. Contrasted to this, only five (3.2 per cent) of the 153 patients without jaundice showed acute necrosis. Three of the sixty-four patients with jaundice showed malignant changes in the liver parenchyma, in forty-four cases no obvious cause for jaundice was observed.

Since the excessive consumption of alcoholic beverages has been considered to be an important etiologic factor in atrophic cirrhosis, the records of these 217 cases were examined as to this point. In forty-six cases (22.2 per cent) there was a clear-cut history of chronic alcoholism (table 5). This group embraced cases of Korsakoff's syndrome, delirium tremens, peripheral neuritis and repeated admissions for acute intoxication.

In a considerable number of cases the moribund condition of the patient on admission precluded the possibility of eliciting an adequate history. In these forty-six cases the history showed marked evidence of chronic alcoholism. In five additional cases the history of the abuse of alcohol was questionable. In all, in forty-six cases (26.5 per cent) of 173 in which an adequate history was available an abuse of alcohol was reported. Were records available on the drinking habits of a greater number of the patients in this series a higher incidence of excessive alcoholic consumption might be expected.

Syphilis was the next most frequent associated condition, being present in twenty-six (12 per cent) cases. Tuberculosis was noted in six (2.8 per cent)

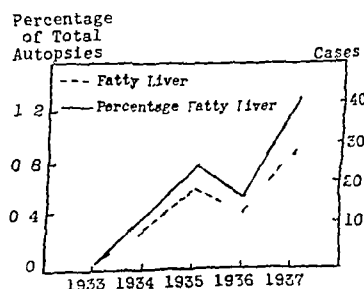

Chart 3—Number of fatty livers observed in relation to the number of autopsies. Data for 1937 estimated on the basis of those collected in the first four months.

COMMENT

Laënnec's (atrophic) cirrhosis is apparently showing a rising incidence. The beginning of this rise coincided with the repeal of the national prohibition law. Since repeal the incidence in our series has been three times that seen during the prohibition period. One fourth of the patients definitely had chronic alcoholism. This factor exceeded all other single known factors in frequency. These facts seem to indicate that the excessive consumption of alcoholic beverages is in some way conducive to cirrhosis of the liver. It probably acts only as a contributing factor. Further study of cirrhotic livers for their mineral content might be profitable.

In his group of sixty-eight cases of true Laënnec's cirrhosis, Ophuls⁶ found a history of alcoholism for thirty-one of thirty-four patients about whom clinical data were available. Assuming, as we have done in this study, that the absence of clinical data was equivalent to a negative history, this incidence equals 45.6 per cent. Even Boles and Clark,⁴ who reject the alcoholic hypothesis, report an incidence of 35 per cent. These observations, in the light of our data, seem too significant to be passed over lightly. The generally increasing addiction to nicotine and the increasing therapeutic use of heavy metals may act with alcohol as aggravating factors.

No insight was gained from this study into the nature of death from "liver insufficiency." Clinical procedures available at present are not adequate for the correct diagnosis of cirrhosis even in 50 per cent of cases, hence the material available is too limited for adequate statistical analysis. Furthermore, the various liver function tests known at present are notoriously inadequate as a true measure of the functional activity of this organ.

The prevalence of fatty changes in livers observed during the second period covered by this report (1933-1937) is worthy of note. The fact that the liver is practically always large and fatty in patients dying with clinically recognizable chronic alcoholism but not presenting classic cirrhosis, and the almost complete absence of this type of change in the liver under other conditions lead to the conclusion that there is an essential relationship between chronic alcoholism and fatty liver.

In considering the cases in which the liver shows a combination of typical cirrhosis and fatty metamorphosis two hypotheses present themselves. 1. These combined lesions represent a comparatively early stage of cirrhosis in which the fatty change is being obscured and submerged by the fibrotic replacement hyperplasia. 2. The fatty change is the true lesion of alcoholism, which has been superimposed on an already existent cirrhosis of, at present at least unknown cause. The correct solution to the problem will have to await direct experimental evidence.

SUMMARY

1. The incidence of Laënnec's type of cirrhosis of the liver is apparently increasing. For the years 1918 to 1932 inclusive this lesion was observed sixty-two times, or in 0.65 per cent of all autopsies. From 1933 to May 15, 1937, it was observed 155 times, or in 1.84 per cent of all autopsies.

2. The excessive consumption of alcoholic beverages seems to be a contributing factor to the development of cirrhosis. In forty-six cases of 173 (26.5 per cent) there was a clear-cut history of alcoholism.

MEDICAL ASPECTS OF SURGICAL
TREATMENT OF HYPERTENSION

IRVINE H. PAGE, M.D.

INDIANAPOLIS

The effort to treat hypertension by surgical as well as medical means is a development of recent years. While the theoretical basis of certain operations used is insecure, some of the results obtained are worthy of serious study. Two operations among the many proposed appear most likely to be of some value. These are resection of the anterior spinal nerve roots¹ and resection of the splanchnic nerves.²

Three and one-half years ago Dr. George Heuer of the New York Hospital and I decided to study intensively the effects of these two operations on patients with hypertension. A plan was put into effect whereby the patients were studied for a long period in the Rockefeller Hospital and transferred to the New York Hospital for operation by Dr. Heuer. They were then returned for further study. In this manner we believed that the study would be as objective as possible.

In all twenty patients have been subjected to section of the anterior spinal nerve roots and nine patients to resection of the splanchnic nerve and the lower thoracic ganglions (Peet technic). It is not my purpose in this brief communication to discuss the literature or review the cases in detail. This has recently been done by Dr. Heuer and me.³ It is my purpose to present a summary of my medical observations and experiences and of the opinions which I have formed during the care of these patients. Dr. Heuer has reviewed the subject from the surgical point of view.⁴ It appeared to be a matter of the first importance to observe our patients for as long as practical before operation to exclude normal fluctuations in the level of arterial pressure and to become thoroughly acquainted with their physical status and emotional pattern. Most patients were not accepted for study unless the date of onset of the disease could be determined with reasonable accuracy from records of physicians and insurance examinations, for we wished to ascertain the probable rate of progress of the disease. The patients were usually studied in the outpatient department for several weeks or months and then admitted to the hospital for a month or more to rest in bed. They were not, except under special circumstances, allowed out of bed. When it seemed desirable, sedatives, such as bromides, chloral preparations and amylal were administered.

Whether it would be wise to select only certain patients for operation was considered, but as no criteria for such selection were known, patients with various

types of hypertension were chosen. This choice has, I believe, been advantageous, because some of the patients responded well who might least have been expected to do so. In short, the criteria usually

barbituric acid is administered as an anesthetic to ascertain the fall in pressure as an index of vascular flexibility.

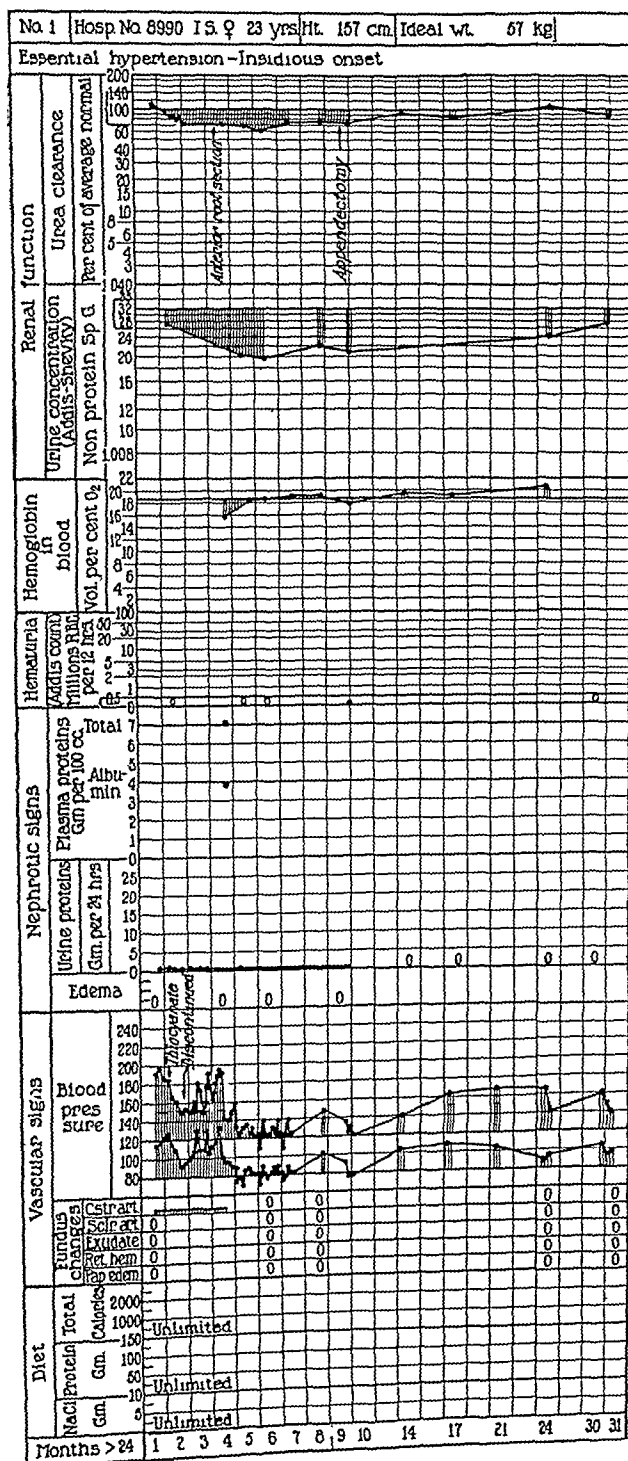

In order to avoid confusion, the classification of the types of hypertension will be briefly reviewed. Essential hypertension is considered a disease with a strong hereditary background. The onset is usually insidious and without ascertainable cause but often follows several years after toxemia of pregnancy or eclampsia. It may occur during the menopause. Vascular and renal changes may be slight or advanced. Morbid cardiac changes may or may not be present. Except for constriction and sclerosis of the retinal arterioles and arteriovenous compression, the ocular fundi are normal. Later in the disease exudates may appear. Secondary glaucoma is not rare. Some patients show more or less well developed neuroses. Some exhibit signs and symptoms such as primitive emotional behavior, blushing, lacrimation, sweating and palpitation, which in many ways appear to imitate morbid stimulation of the diencephalic centers (the "hypertensive diencephalic syndrome").⁶ Death is usually due to cardiac failure, apoplexy or uremia. Great variability is exhibited in the rapidity with which the disease progresses. At any time progress may be accelerated and signs appear suggesting that it has become malignant.

Malignant hypertension, conversely, is considered a syndrome which runs its course in a short time, rarely more than four years. It is often heralded by the appearance of hemorrhage in the retinas and blindness. Papilledema occurs early. Symptoms and signs are often surprisingly slight until a few weeks, or even days, before death. The arterial pressure rises rapidly, but the diastolic pressure is usually proportionately higher than the systolic, producing a low pulse pressure. Renal efficiency may fall rapidly to a uremic level but in some cases is not much affected. Hemorrhages and exudate may all but obliterate the arterioles in the retinas. Edema of the retina and often detachment occur. These patients should be distinguished from a type occasionally seen during and for a year or more after pregnancy who have hemorrhages in the fundi. The hemorrhages are usually reabsorbed, and while the pressure may remain elevated, the course of the disease is ordinarily markedly different from that of malignant hypertension.

EFFECTS OF SECTION OF THE ANTERIOR SPINAL NERVE ROOTS

The operation was usually performed in two stages by Dr. Heuer. The first stage consisted of a laminectomy, and from three to five days later the dura was opened and the nerve roots cut. The blood pressure usually fell to normal levels during both operations but rose moderately during the next few days. The patients suffered considerable pain in the back for several days after operation but in most cases convalescence was uneventful. Some days were required before normal bowel function was reestablished, and some of the patients had difficulty in urination. During convalescence fluctuations of blood pressure were marked, but after several weeks it became more steady.

First, consideration will be given to the effects of the operation on the arterial blood pressure. I have gathered these results into tabular form, arbitrarily taking the average pressure over a period of several days every

six months after operation Much more complete data will be found in the charts recently published by Page and Heuer^{2a}

Three of six patients with essential hypertension who exhibited signs and symptoms of the "hypertensive diencephalic syndrome" showed sustained reduction in blood pressure after operation, while the pressure of three others rose to the preoperative level during the course of twenty-four months Of three patients without marked demonstrable vascular changes, but with

appears to be very slowly falling after one year This is not due to cardiac failure

The symptomatic improvements are out of proportion to the fall in blood pressure Particularly striking was the disappearance of headaches, lessening of the ease with which the patients became fatigued and loss of the nervousness, tenseness and irritability often so characteristic of the disease

No change in renal efficiency, as measured by urea clearance or ability to concentrate urine, was observed

* These numbers refer to the detailed case reports in a paper by Page and Heuer^{2a}

immoderately high arterial pressure, two exhibited considerable reduction and one did not Four of five patients with marked vascular changes showed only a temporary fall, and one exhibited a marked fall about ten months after operation Eight patients with malignant hypertension were subjected to operation In four the pressure was not influenced significantly, while in four others definitely lower levels were established

While in most of the patients with essential hypertension a definite trend of the blood pressure upward was observed two years or more after operation, in others the lower levels have persisted In no case has the blood pressure fallen to and remained at normal levels, allowing one to speak of a cure In one of the patients with malignant hypertension the pressure

which could be referred directly to the operation When renal function was decreasing as a result of the disease, it continued to do so It is my opinion that if change in renal function occurs it is associated more closely with the general clinical condition of the patient than with any direct effect the operation may have on the kidneys themselves

The effect of the operation on the eyegrounds was in some cases remarkable Relaxation of the constricted arterioles occurred in twelve cases In one case of malignant hypertension complete reabsorption of hard white exudate occurred and hemorrhages and papilledema disappeared The morbid changes in the patient's eyegrounds were marked Clearing of such extensive changes I have never seen before, though it may occur in rare cases In a second patient with malignant hyper-

tension there was also marked change for the better, but such extensive destruction had already occurred that it was hardly possible for complete repair to take place. Of interest is the fact that in one patient suffering from severe secondary hypertensive glaucoma the intra-ocular pressure became normal after operation and has remained so for twelve months.

Careful and repeated roentgen studies showed that slight reduction in the size of the cardiac shadow occurred in eight cases. For the most part no change was observed in the electrocardiogram. In two patients the T waves, which had been inverted in lead I, became upright after operation.

Disability as a direct or indirect result of the operation has not been observed. None of the patients required abdominal binders to support the paralyzed portion of the abdominal wall, though many of the women wore corsets, as had been their custom. For several months after operation some of the patients complained of stiff or painful back muscles, but the complaints of all have disappeared. Although the

operation is extensive, it cannot be called disabling, as performed by Dr. Heuer. I have observed no clinical signs or symptoms in any of the patients even after three years which suggest inadequate tissue oxygenation as a result of the lowered blood pressure.

Section of the anterior spinal nerve roots is a difficult operation for the surgeon and has definite dangers. One patient died shortly after closure of the dura. She had seriously reduced renal function and was totally blind. The operation was performed in one stage. In the light of our experience we should not now attempt the operation on a patient with such advanced malignant hypertension, and if it was performed it would be done in two stages. One patient died three days after laminectomy from streptococcal meningitis. Dr. Heuer feels that this was due to a break in surgical technique. One patient with malignant hypertension had transverse myelitis at the eleventh thoracic segment, with paralysis of the legs, although only the laminectomy was performed. The blood pressure fell to a level which is practically normal and has remained at a level of from 130 to 170 mm of mercury for a year and a half. There has been moderate return of sensation in the legs and slight return of motor power. Renal function was unchanged. This accident was serious and warns that the operation has inherent dangers.

SUMMARY

It may be said that the best clinical results have been obtained in two groups of patients. Relatively young persons with essential hypertension, who exhibited signs and symptoms of the "hypertensive diencephalic syndrome," and patients with malignant hypertension. Older patients suffering from hypertension of long standing do not appear to have been benefited by this operation. The question arises whether as good results could have been obtained by medical measures, such as treatment with sodium thiocyanate and rest in bed. I have employed such treatment in many cases, often with good results. I venture to suggest that the symptomatic relief is not as great as with operation, though this has not been proved. Improvement in the condition of the morbid ocular fundi is especially noticeable after operation and is, I believe, unusual after medical treatment. The effects of operation on malignant hypertension appear to be without parallel in medical treatment.

In my opinion the majority of patients with essential hypertension can still be treated best by medical means. However, operation may be desirable in the early stages of malignant hypertension and for young patients exhibiting the "hypertensive diencephalic syndrome."

Opposed to the good results that have been achieved are the accidents which occurred in three cases. Two of these could probably have been avoided and are not likely to happen again, while the third, the occurrence of transverse myelitis, still remains a serious hazard. Consequently, if an operation that is less difficult and dangerous is devised which offers equal results in selected cases, it will doubtless find a place in the therapeutics of hypertension. Perhaps Adson and Allen's new operation is a step in this direction.

SPLANCHNIC NERVE RESECTION

The operation of supradiaphragmatic splanchnic nerve resection combined with removal of the lower thoracic sympathetic ganglions has been practiced extensively in this country. Dr. Heuer has performed it on nine patients whom I have studied. An effort was made to select a small but representative group, including young persons in whom the disease was benign, patients in whom the menopause had just passed, and patients in whom the disease was malignant.

The operation is a much less drastic one than section of the anterior spinal nerve roots, and there has been no operative mortality or serious complications. In some of the patients the operation was performed on one side and a week or more later on the other, while in others it was carried out in one stage.

During the operation and for days or weeks afterward the arterial pressure was markedly reduced without significant change in renal efficiency. But within nine months the pressure had returned in all cases to, or close to, the preoperative level (table 2).

Subjective improvement was marked in most of the patients with essential hypertension. This consisted of lessening in the frequency and the severity of head aches, and lessening of fatigue, nervousness, tenseness and irritability. But in three improvement lasted less than a year. Improvement in three patients with malignant hypertension was also transient.

Renal efficiency appeared to be unaffected by operation although only one patient exhibited low urea clear-

ance. It also appeared to have no significant effect on the heart as judged by electrocardiographic records or roentgenograms. Nor was any constant change observed in the pressor response to immersion of the hand in cold water (Hines-Brown test).

In one case of essential hypertension and two cases of malignant hypertension, papilledema disappeared after operation but it reappeared in the latter cases within several months. Reduction in the intensity of the constriction of the retinal arterioles occurred in all of the cases of malignant hypertension except one, demonstrating that arteriolar relaxation occurs in regions other than those denervated. In most of the patients constriction returned after several months.

It thus appears that while resection of the splanchnic nerves produces many of the effects that are observed after section of the anterior roots, they are often more transient. If a larger group had been operated on doubtless the results would have been more striking in a small percentage. From the point of view of technical ease and lack of dangerous complications, it is to be preferred to section of nerve roots but, conversely, the good results appear to be somewhat more transient in most cases. In no case was I able to detect that the patient had been harmed by the procedure.

It is my belief that surgical methods which are designed to aid in the treatment of hypertension are still in the experimental stage. The results are not as good as had been hoped for by some and not as bad as had been predicted by others. The operations which are now employed are probably far from the best, but it is becoming clearer what may be expected from the two operations which have here been discussed.

It is by no means certain what the theoretical basis is, in cases of hypertension, for performing operations in which large vascular areas are denervated. Normal as well as abnormal vasomotor impulses are naturally prevented from reaching normal or abnormal vessels to cause hypertonus. I know of no conclusive evidence that the nervous impulses are abnormal or that the vessels are unusually sensitive. It is of much interest that after operation vascular constriction in the eye-grounds relaxes. It is presumed though not proved, that relaxation also occurs in the denervated area. Possibly the fall in blood pressure which takes place after operation causes a reflex dilatation of the vessels in the head somewhat similar to that found in animals⁸ when the blood pressure falls to low levels. Whether the morbid changes in the fundi regress because of relaxation of the vascular spasm, reduction of the intracranial pressure or both cannot be affirmed with certainty. Measurement of the intraspinal pressure before and after operation has shown marked reduction when the pressure was elevated before operation. It seems that both factors are responsible for the changes in the eye-grounds.

It does not appear probable to me that a nonspecific operation would achieve the same results as root section. This opinion is strengthened chiefly by observation of one patient on whom a laminectomy was performed but who, for reasons of his own, refused the second stage of the operation, i. e., opening of the dura and section of the anterior spinal nerve roots. After operation the blood pressure soon regained its preoperative level and during the course of the next

six months had appreciably exceeded it. If the shock and trauma of the operative procedure in general are responsible for the effects of the complete operation this patient should have exhibited as well marked results as those in whom the anterior roots were actually severed, since laminectomy itself is by far the longest and most shocking part of the whole operation.

MANAGEMENT OF POSTOPERATIVE DISTENTION AND ILEUS

THE USE OF PROSTIGMINE IN 175 CASES OF
ABDOMINAL SURGERY COMPLICATED BY
PARALYTIC ILEUS AND POST
OPERATIVE DISTENTION

JOHN R. HARGER, M.D.

Attending Surgeon Cook County Garfield Park and Illinois
Masonic Hospitals

AND

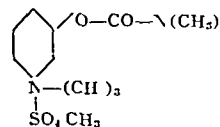

J. LESTER WILKEY, M.D.

Resident Surgeon Cook County Hospital

CHICAGO

One of the grave postoperative complications is intestinal atony. The paralysis and distention accompanying intestinal atony contributes materially to the mortality of diffuse peritonitis. The patient's dread of abdominal surgery is deeply tinged by fear of "gas pains," which are familiar even to the general public as the prominent symptom of a distressing, distention-hidden postoperative course.

It is not surprising therefore, that a wide variety of drugs, as well as a large number of mechanical procedures, have been developed to combat this unwelcome postoperative complication. One of these, physostigmine (eserine), was early used in the treatment of intestinal atony, but its stimulating action on the parasympathetic system may be evidenced not only by an increased intestinal peristalsis but also by bradycardia, dyspnea, miosis and a fall in blood pressure. Stedman and his co-workers¹ in their work on substances capable of inducing responses similar to those induced by physostigmine investigated the mono-alkylcarbamic acids. Their investigations culminated in the synthesis of dimethyl-carbamic ester of 3-hydroxyphenyl-trimethyl-ammonium methylsulfate, known as prostigmine. Its structural formula is

PHARMACOLOGY

To quote, in part, from a recent editorial:

It [prostigmine] is a synthetic compound resembling physostigmine but differing chemically from this alkaloid by its less complicated structure and its greater stability. It is marked by a pronounced action on peristalsis, a less pronounced miotic effect and an almost complete absence of cardiac by-effects. These characteristics have been carefully delineated

From the Cook County Hospital

through the work of Aeschlimann and Reinert, Berk, Feldberg, Rothschild, and many others. Inspection of the massive bibliography reporting the clinical use of this product leaves one with the definite conviction that it must possess clinical merits distinctly above that of therapeutic agents formerly used.

Certain of the studies, from well known clinics, are obviously scrupulously well controlled and cover very large numbers of cases. Reports covering the use of the drug running into well over a thousand cases indicate that it is harmless, clinically effective and has definite advantages over physostigmine.

The work of the authors mentioned⁴ definitely established the efficacy of prostigmine as a peristaltic stimulant and the lessened incidence of toxic or untoward by-effects attending its use. The pharmacologic work of Aeschlimann and Reinert² established these facts. Physostigmine, in concentrations of 1:1,000, often stopped the isolated frog heart in diastole, while the same dilution of prostigmine was without effect beyond a slight decrease in the amplitude of contractions. A 1 per cent solution of physostigmine always stopped the frog heart in diastole, while prostigmine in like concentration had little or no effect. In doses up to 0.1 mg per kilogram prostigmine was found to have practically no effect on the blood pressure; this dosage is much more than that required to induce peristalsis. In doses approaching toxicity, the action of prostigmine is similar to that of physostigmine. Even in extreme dilution, 1:5,000,000 and 1:7,500,000, prostigmine still caused contraction of the isolated rabbit intestine. The effective intravenous dose stimulating the bowel in situ was found to be 0.02 mg per kilogram.

CLINICAL REPORTS

Levis and Axelman⁵ used prostigmine to prevent postoperative atony and therefore began the administration of prostigmine shortly after, or at the time of, operation and continued medication as necessary. Prostigmine (1 cc of a 1:4,000 solution) was given at intervals of from four to six hours until the condition of the patient warranted discontinuance of the medication. The last injection of prostigmine was followed by the administration of a soap-suds enema. Levis and Axelman found prostigmine valuable in combating distention and "gas pains." Prior to the use of this agent, from 60 to 75 per cent of their patients complained of subjective symptoms or exhibited objective signs of intestinal atony; the administration of prostigmine reduced the percentage to a negligible minimum.

Schlaepfer⁶ begins prostigmine injections (1 cc of a 1:2,000 solution) from eight to ten hours following the operation and repeats every eight hours until normal peristalsis is evidenced. Schlaepfer injected prostigmine intramuscularly and considers it "a very reliable agent to restore early normal peristalsis following laparotomy."

Baker,⁷ in discussing the prevention of distention following kidney operations, says that, although a large enough series had not as yet been conducted, he is of

the opinion that prostigmine is the most efficient prophylactic measure available. Cases of obstinate distention, developing despite all efforts at prophylaxis, are usually amenable to insertion of a duodenal drainage tube and the injection of prostigmine (the 1:2,000 solution). The injection should be given at intervals of from thirty to sixty minutes until three or four doses have been given or until distention has been relieved. In stubborn cases, the duodenal tube should not be removed until active peristalsis is manifest.

Uznanski⁸ applied prostigmine both before and after operation. He found prostigmine valuable both as a prophylactic against and as a treatment for paralytic ileus and distention.

We have used prostigmine (the 1:4,000 solution) over a period of three months at the Cook County Hospital in 175 cases of abdominal operations. As will be seen from the representative case reports briefly abstracted, the conditions necessitating surgery were varied. In addition to the use of prostigmine in surgical cases, we have also applied it in uremia with associated paralytic ileus with gratifying results, and in one case of obstructive jaundice with coronary heart disease. In this instance a slight rise in blood pressure was noted, which rise, however, aided materially in the prognosis. We have found in prostigmine a very satisfactory method of controlling postoperative distention. No signs of drug intoxication were seen, nor were by-effects on the eye observed. There was no obvious evidence of hyperperistalsis and no complaints of excessive cramps. Except where noted, no adjuvant measures, such as enemas, stipes, heat cradle and the like, were used to enhance the action of prostigmine. The 1:4,000 solution of prostigmine methyl sulfate administered subcutaneously, was used in all cases. If possible, prostigmine medication was started preoperatively.

REPORT OF CASES

CASE 1—A S, a white youth, aged 18, admitted to the hospital Oct 28, 1936 with acute appendicitis of fifty three hours' duration, was found at operation to have a ruptured appendix, with diffuse peritonitis. The appendix was removed and the abdomen closed without drainage.

On the first postoperative day there was moderate distention. No peristaltic sounds were heard, and no gas or feces were passed.

On the second postoperative day there was distention, no gas or feces having been passed since operation. The patient was given one ampule of prostigmine (0.00025 mg of prostigmine methyl sulfate) at 10 a. m., the dose being repeated at 12 noon and 2 p. m. At 3:30 great quantities of gas were passed and peristaltic sounds were heard at the rate of 22 per minute.

On the third postoperative day prostigmine was given every two hours for four doses. The peristaltic sounds were 25 per minute. The feces and gas were passed twice in six hours.

The blood pressure on admission was 110 systolic, 80 diastolic, and at no time was it above 114/85 or below 108/90. The pupils appeared normal throughout the prostigmine medication. The patient did not complain of abdominal pain at any time during the course of prostigmine. An uneventful recovery ensued.

CASE 2—J V, a Negro, aged 36, admitted to the hospital Oct 29, 1936, with a history of a scrotal hernia of four years' duration had blood pressure of 128 systolic, 90 diastolic on admission. He was given two ampules of prostigmine two hours before operation and one additional ampule one hour before being taken to the operating room. Eight feet of intestine was found in the hernial sac at operation. The intestine however, was entirely collapsed and was easily replaced into the abdominal cavity.

On the first postoperative day, peristaltic sounds were 14 per minute. No gas or feces were passed, but the patient was free from distention. No prostigmine was given.

On the second postoperative day there was moderate distention. The peristaltic sounds were reduced to six per minute, and the abdomen was definitely tympanitic on percussion. Four ampules of prostigmine were given at two hour intervals. During the evening, four hours after the last dose, the patient passed considerable quantities of gas, but no hyperperistalsis occurred. The peristaltic sounds increased to seventeen per minute. A slight increase in blood pressure was noted at that time, 132 systolic, 94 diastolic.

On the third postoperative day both gas and fecal material were passed twice within seven hours. Prostigmine was continued three ampules being administered, at the rate of one every two hours. The blood pressure was 130 systolic, 90 diastolic, and, although a slight miosis was evident, the pupils reacted normally to light and in accommodation. The patient was given 2 ounces (60 cc) of liquid petrolatum. He volunteered the information that he felt "fine," and, except for a superficial wound infection which promptly responded to hot moist dressings, made an uneventful recovery.

CASE 3—C M, a white man, aged 23, admitted to the hospital Oct 29, 1936, had a diagnosis of subdiaphragmatic abscess. At operation the ninth rib was resected and the abscess drained.

On the first postoperative day, distention was present, and only three or four peristaltic sounds were heard per minute. No gas or feces were passed. Prostigmine was begun, and one ampule was given every two hours for four doses, the last injection being given at 5 p m. At 7 o'clock the peristaltic movements were from seventeen to twenty per minute, and gas was passed, resulting in considerable relief. A normal bowel movement occurred at 10:30.

On the second postoperative day, the patient was quite sick, with a temperature of 103.4 F, the abdomen was moderately distended, and peristaltic sounds were from twelve to thirteen per minute. Three ampules of prostigmine were administered during the space of six hours, resulting in an increase of peristaltic sounds to twenty per minute, and two bowel movements were accompanied by much gas.

On the third postoperative day the patient was extremely ill and markedly distended. A diagnosis of generalized peritonitis was made. Four further doses of prostigmine were given, the patient passed gas and had a normal bowel movement. Despite the improvement following the decrease in distention, he died at 8:10 p m.

There was no rise in blood pressure noted and the pupils remained normal in size throughout the postoperative course.

CASE 4—B M, a white man, aged 27, admitted to the hospital Nov 3, 1936 with a diagnosis of acute appendicitis of thirty six hours duration seemed in excellent condition, with no distention evident. At operation, an acute phlegmonous appendix was removed and the abdomen closed without drainage. There was no preoperative prostigmine medication.

On the first postoperative day the peristaltic sounds were twelve per minute. No distention was present but no gas or feces were passed.

On the second postoperative day at 8 a m, the abdomen was markedly distended, its crest being five finger breadths above the pubo ensiform line. No gas or feces had been passed, and peristalsis occurred at the rate of from three to five movements per minute. Two ampules of prostigmine were given immediately, and then one ampule every three hours for four doses. At 4 p m the abdomen was still distended with tympanitis. Peristaltic sounds had increased to eighteen per minute, although no gas had been passed. At 7:30 a large quantity of gas, mixed with feces, was expelled. Two ampules of prostigmine were given during the night.

On the third postoperative day the abdomen was soft and only slightly distended. Prostigmine was given at 9 a m and again at 11 o'clock. Following a high enema the patient passed a large quantity of gas and feces and was subjectively much improved.

An uneventful recovery ensued. The patient became ambulant on the eighth day and returned home on the tenth day after

operation. The blood pressure rose from 134/86 to 142/98 during prostigmine medication, no pupillary changes were noted at any time.

CASE 5—A Mc, a white man, aged 32, admitted to the hospital Nov 4, 1936, had fallen from a scaffold while painting. He was in shock, with the pulse 140, temperature 97.6 F, respiration rate 32, blood pressure 80/65, and the skin cold and clammy. The blood count was hemoglobin 95 per cent, red blood cells 4,800,000, white blood cells 9,400. Because of the abdominal distention, the possibility of a ruptured viscus was considered. However, a catheterized specimen of urine revealed no blood, and fluoroscopy showed no free air under the diaphragm or above the liver. There were no masses felt in the abdomen and rigidity was not apparent. The patient responded to external heat, intravenous fluids, stimulants and reversed Fowler's position, twelve hours after admission he was considered to be out of shock, with pulse 100, respiratory rate 22, blood pressure 110/80, temperature 99.8 F. Marked distention was present, however, and an enema was given without results. No gas or feces had been passed since the accident. Two ampules of prostigmine were given at once, and subsequently one ampule was given every two hours for five doses. Within eight hours the peristaltic sounds had increased from two to three per minute to from fourteen to twenty-one, and the patient passed much gas and some fecal material. The next day three ampules of prostigmine, one every two hours, were injected. Two bowel movements resulted.

The patient suffered several fractured ribs and paralytic ileus developed. The results of prostigmine medication were most satisfactory, with no evidence of blood pressure or pupillary changes.

CASE 6—J V, a white man, aged 68, was transferred, Nov 4, 1936, from the medical ward with a diagnosis of regional ileitis presenting partial obstruction. Although slight distention was present, prostigmine was not administered preoperatively. At operation, a regional ileitis involving the lower 12 inches of the ileum was found, the involved wall being markedly thickened, with distended bowel above the indurated area. Resection was not done but an anastomosis was performed above the obstruction.

On the first postoperative day the peristaltic sounds were seven per minute and there was moderately severe distention. A Levine tube was inserted and parenteral fluids were administered.

On the second postoperative day the distention was increased. The patient appeared quite ill. At 8 a m two ampules of prostigmine were given, followed by an equivalent dose at intervals of two hours. No gas was passed all day, however.

On the third postoperative day prostigmine, one ampule every two hours was continued. At 1 p m the peristaltic sounds had increased to twenty-two per minute and the patient passed a huge quantity of gas mixed with considerable fecal material. At 8 o'clock no distention was evident.

On the fourth postoperative day one ampule of prostigmine was given every three hours. At 4 p m a normal bowel movement occurred, and gas was passed freely all day.

The blood pressure and pupils remained unchanged throughout the postoperative course. An uneventful recovery ensued.

CASE 7—A M, a white man aged 32, admitted Nov 6, 1936 with a diagnosis of chronic appendicitis, presented an excellent opportunity for a study of the value of preoperative prostigmine medication. He was given two ampules three hours before and one ampule immediately preceding operation. At operation the bowel was entirely collapsed and consequently presented no difficulty during the intra abdominal manipulations necessary for the removal of the appendix.

The first postoperative day no distention was present, some gas was passed, but the patient had no bowel movement.

The rest of the postoperative course was entirely uneventful. Further prostigmine medication was not needed. There was no distention at any time, and a normal bowel movement occurred on the third postoperative day. A semisolid diet was given on the fifth postoperative day and the patient was ambulant on the eighth day. No change was noted in the patient's blood pressure, pupils or pulse as a result of prostigmine medication.

CASE 8—N A, a white boy, aged 14 years, admitted Nov 6, 1936, following injury to the pelvis sustained in an automobile accident, was in severe shock and, in addition, presented a rigid abdomen with a definite mass in the right lower quadrant. He was treated for shock, during which time (six hours) it was decided that laparotomy should be performed in order to determine the extent of injury. He was given two ampules of prostigmine before surgery. When the abdomen was opened, the entire bowel was collapsed, making discovery of a large retroperitoneal hematoma a simple matter. The abdomen was closed without further intervention.

The first postoperative day the general condition was poor. A scultetus binder was applied, and because the peristaltic sounds were few, from three to four per minute, and no gas or feces had been passed, Wangensteen decompression was instituted. Enemas were also employed without results. A diagnosis of paralytic ileus was made and solution of posterior pituitary, one ampule every two hours for four doses, was given without relief.

On the second postoperative day, prostigmine medication was reinstituted, one ampule being injected every two hours. After the fourth dose the peristaltic movements had increased to ten per minute, and the patient passed some gas, thereby relieving the distention appreciably. Seven hours later, the prostigmine being continued throughout, a bowel movement occurred.

The patient recovered satisfactorily although the subsequent course was rather hectic. Two transfusions were necessary, and occasional enemas were required to enhance the action of prostigmine. This case is particularly interesting not only because of the extreme degree of ileus but also because frequent prostigmine dosage, even in a 14 year old boy, resulted in no untoward effects. The frequency of administration was double that suggested by the manufacturer, as indeed, it was in most of our cases but no signs of toxicity occurred.

CASE 9—M D, a Negro, aged 39, admitted to the hospital Nov 7, 1936 with a diagnosis of chronic cholecystitis and cholelithiasis, in addition presented evidence of marked bowel spasticity and distention. Two ampules of prostigmine were given at 9 p m the night before the operation another ampule at 8 a m the following morning and one immediately preceding the operation. Both the large and the small bowel were found to be totally collapsed. The gallbladder was easily found and removed without difficulty and the abdomen was closed with the liver bed drained.

On the first postoperative day there was no distention, the condition was good.

On the second postoperative day there was slight distention no gas or feces were passed there was some vomiting.

On the third postoperative day the abdomen was moderately distended. Solution of posterior pituitary, two ampules, was given at 8 a m and then one ampule every two hours for distention. Gas was passed at 4 p m but the marked elevation of blood pressure, 20 points systolic, convinced us that solution of posterior pituitary should not be used further.

On the fourth postoperative day prostigmine was administered for distention—two ampules at once, repeated in two hours and followed by one ampule every two hours for four doses. At 9 p m both gas and feces were passed. The blood pressure remained normal.

On the fifth postoperative day gas and feces were again passed, with relief of distention. Prostigmine was given every two hours for four doses, with excellent objective and subjective results. After the fourth day slight contraction of the pupils was noted, and from then on an uneventful recovery ensued.

CASE 10—B V, a white man aged 52, admitted to the hospital Nov 17, 1936, with a diagnosis of acute intestinal obstruction, had suffered for two days from vomiting abdominal distention and complete obstipation. A cecostomy was performed, on operation, the site of obstruction was thought to be the rectosigmoid junction.

On the first postoperative day the patient's condition was poor. Repeated enemas returned clear.

On the second postoperative day a slight quantity of gas escaped when the cecostomy was opened, along with a small

amount of fecal material. Distention was extreme, but no further measures were instituted.

On the third postoperative day gas continued to be expelled in small quantities through the cecostomy. At 8 a m two ampules of prostigmine were given, and one ampule was given every two hours thereafter for six doses. At 6 p m a large quantity of gas was expelled, together with considerable fecal material.

On the fourth postoperative day, distention was much reduced. Feces and gas were passed freely through the cecostomy, and the patient's condition was considered excellent. Four doses of prostigmine were given, one ampule every three hours.

On the fifth postoperative day, distention was completely relieved, there was no pain and gas and feces were passed freely. No further prostigmine was given.

The subsequent course was entirely without incident. An exploratory laparotomy on the twentieth postoperative day revealed the presence of a carcinoma of the sigmoid with extensive metastases. The blood pressure remained normal throughout prostigmine administration the pupils however, became slightly sluggish in accommodation and miotic.

CASE 11—W a white man, aged 47, admitted to the hospital Nov 18, 1936, in severe shock, showed evidence of peritonitis and pneumoperitoneum. No preoperative medication was administered. At operation a ruptured gastric ulcer was found, and fluid and gastric contents were found in the abdominal cavity. The ulcer was sutured and the abdomen closed without drainage.

On the first postoperative day, marked distention and tympanites occurred. Peristaltic sounds were only four per minute. Wangensteen decompression was begun and parenteral fluids were given. No feces or gas were passed.

On the second postoperative day, distention was still marked no gas was passed nor were any peristaltic sounds heard. Solution of posterior pituitary was given one ampule every two hours for five doses. No gas had been passed by mid night, and enemas were entirely without results.

On the third postoperative day at 8 a m two ampules of prostigmine were administered followed by a similar dose at 10 o'clock. Doses of three ampules were then given at intervals of two hours. At 2 p m a low saline enema resulted in the expulsion of much gas and fecal material.

On the fourth postoperative day distention was much diminished and the patient was passing gas freely. Prostigmine was continued in one ampule doses every three hours for four injections and a normal bowel movement occurred at 7 p m.

On the fifth postoperative day peristaltic sounds were eighteen per minute and the distention had vanished. The patient went on to recovery with no complications. The blood pressure and the eyes were normal throughout.

COMMENT

Prostigmine has a wide margin of safety. Although intervals between doses of from four to six hours are recommended, and but one ampule per dose we have constantly given the drug at two hour intervals to patients ranging in age from 14 to 68 years with no demonstrable ill effects. Reports hitherto have recommended longer intervals than two hours. Our results convince us that prostigmine may be given more frequently and in larger doses with assurance of a satisfactory response and no danger of untoward by-effects.

SUMMARY

- 1 Prostigmine was used in 175 cases.
- 2 Prostigmine, a 1:4,000 solution of the dimethylcarbamate ester of 3-hydroxyphenyl-ammonium methylsulfate, is a satisfactory agent for the prevention or treatment of distention and paralytic ileus.
- 3 In our series of cases the administration of prostigmine was followed by excellent results with a low incidence of by-effects.

4458 West Madison Street

CONTRACEPTION IN PRIVATE
PRACTICE

A TWELVE YEAR EXPERIENCE

LOVETT DEWEES, M.D.

APPROPRIATE, PA
AND

GILBERT W. BEEBE

Of the National Committee on Maternal Health, Inc.
NEW YORK

The contraceptive service reported here developed within a general family practice in a residential suburb of a large city. The initial impulse to study contraception came twenty years ago from the requests of professional patients acquainted with the beginnings of a literature on the subject. An enduring stimulus has been provided by the succession of women patients in distress from unwisely pregnancies. In the last ten years it has become a routine matter to discuss contraception with postpartum patients and to teach better methods whenever they are needed and welcomed.

INDICATIONS

The indication for contraceptive knowledge and advice is, broadly considered, marriage. Of course, some patients have come in the late thirties or early forties because they wished to have no more children, and others have been referred because of obvious physical or mental contraindications to pregnancy. But in recent years an increasing number of young women have come to learn how to plan and space their children. Those advised premaritally have sought to postpone the first pregnancy while gainfully employed or until they felt better adjusted. Women usually need from one to two years of protection after childbirth before conceiving again.

METHODS

About 94 per cent of all the patients advised have been given the occlusive vaginal diaphragm with jelly. This paper, therefore, is essentially a report and discussion of the use of that method. It has become the preferred contraceptive of a large majority of couples. The most frequent structural conditions interfering with the fit of the diaphragm have been cystocele and marked relaxations of the pelvic floor and vaginal walls with some uterine descent. Retroversion of the uterus has seldom been a contraindication, although it has often required a special manner of insertion. Sound anterior vaginal structure and other conditions which allow the rim to stay well up against the rear face of the symphysis pubis are essential to the use of the circular diaphragm. The Matrisalus was designed to support a sagging anterior wall but in this series has rarely been successfully adjusted. In recent years a Dumas pessary, a rather broad, shallow, all-rubber cap, has been found to fit well high behind or beyond the bulging cystocele.

In early years only starch-glycerite jellies with 1 or 2 per cent lactic acid were prescribed for use with the diaphragm. In time these have been replaced by modified starch-glycerite and by vegetable gum preparations also dependent on acidity¹ for spermicidal action. Modified soap creams, usually containing paraformaldehyde, have also been employed. The variety of modern jellies makes it possible to individualize the prescription of jelly, and the trend away from high

percentages of glycerin has reduced the frequency of complaints of messiness. Because one patient will complain of this jelly and another of that, judgment or trial and error must find the appropriate prescription in each case.

Premarital patients have often been advised in the use of the condom or condom with jelly and later fitted with the diaphragm, but a large proportion of the premarital patients readily learn the diaphragm technique. Premarital examination and discussion present real opportunities for educational and preventive work.

For the details of fitting and teaching, the reader is referred to the discussion in *Control of Conception* by Dickinson and Bryant.² Judgment in fitting comes with experience and repeated check-up examinations. A routine check-up soon after fitting has not always been found possible but is essential for premarital and recently married patients. Emphasis has rather been placed on adequate initial instruction. Success in teaching depends on painstaking work with each patient. From a half to three quarters of an hour may be required for office explanation and practice by the patient.

CHARACTERISTICS OF SAMPLE STUDIED

In the twelve years that ended in 1936, contraceptive advice was given to 884 white patients. One fourth of these were of the premarital group. The median³ age at the first contraceptive consultation was 27.3 years, and the median duration of marriage 4.3 years for those who were already married. The median married patient reported two previous pregnancies, but one fourth of the married women had never conceived. The patients came mainly from upper middle class homes with annual incomes ranging roughly from \$3,000 to \$10,000. One fifth might be termed wealthy while three fourths were of the professional or business middle class and one twentieth of the laboring class. Seventy per cent of those who reported their education had received some college training or the equivalent. Twenty-three per cent had progressed no further than high school and 7 per cent no further than elementary school. Ninety-four per cent were Protestants.

NATURE OF THE INVESTIGATION

The patients who were also part of the family practice usually had complete follow-up records because of the many opportunities to study them. The patients in a part of the series, increasing rapidly since 1930, were referred by their friends or physicians. Since they applied only for contraception, they gave less opportunity for close observation. One fourth of all those advised were never reached again for follow-up.

In 1936 a cooperative arrangement was made with the National Committee on Maternal Health for an intensive study of the available case material, and a follow-up by letter and interview was attempted in all cases in which the history was incomplete. The letter elicited slightly more than a 50 per cent response. Analysis of the case material extant prior to this follow-up indicates that the women who answered the letter had had proportionately the same number of unplanned pregnancies as those who failed to answer. But it also shows that those who answered had previously reported relatively many more planned pregnancies than those who did not respond.

¹ For a discussion of acidity see Shedlovsky, L. (Some Acidic Properties of Contraceptive Jellies. *J. Contraception* 2: 147-153 [Aug. Sept.] 1937).

³ That is, 50 per cent were above and 50 per cent below this age. Because of the nature of the distributions the median is a more representative value than the mean.

ACCEPTABILITY OF DIAPHRAGM AND JELLY

The frequency with which patients have persevered with a contraceptive method is one measure of its acceptability. Of all those on whom reports are available, 83 per cent were using the method at the time of the last follow-up entry. But many of those who stopped no longer needed protection against pregnancy, as table 1 indicates. The refusal rate, therefore, may well be from 15 to 20 per cent, but lack of follow-up on one fourth of the patients originally seen seriously limits the value of this estimate. The low frequency of failure as a reason for discontinuance results from two conditions: first, some patients who had unplanned pregnancies recognized the fault as their own and resumed the method with success later, and, second, a number of the patients reporting unplanned pregnancies gave no indication of whether or not they resumed the method at the termination of the pregnancy. One might expect failure with the method to be given greater relative importance in a list

TABLE 1—*Alleged Reasons for Discontinuing Diaphragm and Jelly*

| Reason for Discontinuance | Patients Known to Have Stopped | |
|---|--------------------------------|----------|
| | Number | Per Cent |
| Cessation of exposure to risk of pregnancy* | 20 | 24 |
| Objections on the part of the wife | 20 | 24 |
| Objections on the part of the husband | 11 | 11 |
| Preference for another method | 16 | 15 |
| Failure with the method† | 12 | 12 |
| Lack of confidence | 3 | 3 |
| Other reasons or several | 6 | 6 |
| Reason unknown | 5 | 5 |
| Totals | 107 | 100 |

* Cessation of exposure includes instances of sterilization, menopause, separation or divorce and pelvic inflammatory disease.

† Patients who felt that their unplanned pregnancies could not be attributed to their own carelessness or errors.

of reasons for discontinuance. The average patient who stopped using the method had tried it for less than nine months, and 45 per cent of those who stopped did so within six months.

While there has been no systematic study of the complaints made by patients who continued using the method, spontaneous objections entered on the records have been tabulated. Six per cent of those followed up complained of discomfort or annoyance from the diaphragm and jelly, and half of the objections were of outright discomfort on the part of the wife. A fourth of these were complaints against the necessity for advance preparation and a sacrifice of best feeling.

In consulting with patients on their contraceptive problems, the doctor has come to appreciate the limitations of the method: it is a less than ideal procedure. A few notes on unfavorable reactions illustrate this point: "I hated it!" "Backache after several hours." "Advance preparation tends to diminish desire." "It produced too much secretion and caused restlessness." "The ideal method would be a suppository or a perfected jelly." The 'cap,' while certainly useful, is a nuisance."

The impression is strong in the physician's mind, although it is not often on record, that many of those who abandoned the method after a trial were women who derived little or no satisfaction from coitus with or without contraception. The 15 or 20 per cent who found the method unacceptable constitute a group

urgently in need of individualized counsel and prescription, and the physician must be prepared to offer other advice even though the risk of pregnancy is greater than with the diaphragm and jelly. As a matter of fact, the risk of pregnancy with any common method can be reduced by careful instruction.

It is equally apparent that the diaphragm and jelly method has offered real advantages to a large majority of patients in private practice seeking contraceptive advice. It is definitely superior to other present methods in point of acceptability to these patients and will serve reasonably well until ideal procedures are developed.

EFFECTIVENESS OF DIAPHRAGM AND JELLY

Published data on the clinical effectiveness of diaphragm and jelly, and in fact almost all data on the clinical effectiveness of contraceptives, have been based on inadequate methods of analysis. The customary procedure has been to enumerate the number of patients who suffered unplanned pregnancy, despite faithful following of instructions, and then to state this number as a percentage of the total number studied. The contraceptive method is then said to have yielded the stipulated percentage of failures. The major statistical defect of this method lies in its neglect of the time factor, overlooked in no other field of vital statistics. The computation of probabilities of birth, death and other vital events is always with reference to time. Unless one takes time into account when measuring the clinical effectiveness of contraceptive methods, one inevitably records higher percentages of failure as longer periods of time are observed. For example, if it is shown that with 100 normal users of a particular contraceptive method three is the average number of pregnancies per year of use, then it is clear that the average number of pregnancies for 100 patients during five years will approach fifteen and that the average for ten years will approach thirty. In other words, the application of this technique gives percentages of failure which have no specific meaning because time is not held constant.

For the reason that they bring time into the calculations in a fashion similar to that currently used for measuring the incidence of vital phenomena, the best available statistical procedures are those developed for fertility measurement by Pearl⁴ and by Sir and Notestein.⁵ Their methods⁶ permit the calculation of a pregnancy rate which is 100 times the number of pregnancies divided by the number of woman-years⁷ of exposure to risk of pregnancy. Exposure to the risk of pregnancy is measured in months and years and is derived by subtracting from the years of marriage falling between puberty and the menopause the time during which the wife was pregnant or was known not to be exposed to the risk of pregnancy because of sterility or abstinence. In addition, in this study, one month in excess of each reported period of gestation has been deducted as an allowance for the puerperium. No consensus has been reached as to the best method for controlling the factor of lactation, which is thought

5 Sir, Reginald, and Notestein, F. W. (a) *Effectiveness of P. H. Control (Milham) Memorial Fund Quart.* 12: 57-68 (Jan.) 1934. (b) *Effectiveness of Birth Control: A Second Study*, *ibid.* 13: 162-171 (April) 1935.

6 Pearl has perhaps more often expressed his results as pregnancies per hundred computed ovolutions.

7 One hundred woman-years would be the exposure of 100 women for twelve months each, ten women for 120 months or the equivalent.

to be associated with infecundity⁸ through absence of ovulation and which therefore probably exerts some yet unmeasured influence on all pregnancy rates except those for first pregnancies and for planned pregnancies. Obviously, pregnancy rates may be computed for exposure with or without contraception, and the difference between a rate for noncontraceptive exposure

TABLE 2—*Pregnancy Rates from Other Studies When No Contraception Was Used and When Some Contraception Was Used, and Pregnancy Rates for this Series Before Advice Was Given*

| Order of Pregnancy* | Pregnancy Rates from Other Studies | | | | Pregnancy Rates from This Study Before Advice Was Given | |
|---------------------------|------------------------------------|-------------------------------|------------------------|-------------------------------|---|------------------------|
| | No Contraception Used | | Contraception Used† | | | |
| | Pearl‡ | Stix and Not- stein§ | Beebe and Gamble | Stix and Not- stein§ | | Beebe and Gamble |
| All pregnancies | 107 | 168 | 99 | 28 | 42 | 41 |
| First preg- nancies | 154 | 268 | 110 | 41 | 52 | 74 |
| Subsequent pregnancies | 86 | 100 | 86 | 27 | 40 | 31 |

* In view of the significant differences between rates for first and rates for subsequent pregnancies the distinction is kept here.

† The rates are based on only that portion of each patient's experience when prelinic contraception was used. Pearl's rates for contraceptors include their experience while not relying on contraception and for that reason are not strictly comparable. His rates for all pregnancies of whites in New York and Chicago were 68 and 63 respectively.

‡ Pearl Raymond Fertility and Contraception in New York and Chicago J A M A 108 1385-1390 (April 24) 1937. Rates for all white women have been calculated from the data there given. Pearl's rates are not by order of pregnancy but by parity of women. In consequence his rates for multiparas include some experience at the higher first pregnancy rate and have been adjusted on the assumption that the multiparas had first pregnancies at the same rate as the primiparas. The unadjusted rates are 107, 154 and 99.

§ Stix and Notestein^{6b}.

|| Beebe G W and Gamble C J. The Effect of Contraception on Human Fertility unpublished data from a manufacturing district in Philadelphia.

and a rate for contraceptive exposure is one measure of the effectiveness of contraception in reducing the chance of pregnancy.

As a basis for estimating the probable fertility reduction accomplished by the use of diaphragm and jelly in this series, table 2 draws on other studies for the pregnancy rates of patients when they avoided contraception and when they used it in some form. Table 2 also includes the pregnancy rates of the patients in this series before they came for contraceptive advice. The rates for noncontraception, while differing markedly with respect to first pregnancies, indicate that pregnancies may be expected at the minimum rate of 100 for each 100 woman-years of exposure when all pregnancies are studied, and from 85 to 105 when second and subsequent pregnancies are considered. Ordinary untutored contraception results in rates from 25 to 50, with differences depending largely on the order of pregnancy, the methods used and the care exercised. The low rates found in this study for the period before contraceptive advice was given indicate an extensive resort to contraception. Since these rates are based on all experience, both contraceptive and noncontraceptive, the contraceptive efforts of the patients in this series were, even before they sought medical advice, above average in efficiency.

While relying on diaphragm and jelly, the patients in this series became pregnant at a rate which is only from 4 to 7 per cent of the rate at which women conceive while habitually practicing no contraception.

8 Cooper J M. Birth Control Washington National Catholic Welfare Council 1923. a summary of medical literature appears on pp 71-73 and 95.

Otherwise stated, their use of the diaphragm and jelly was from 93 to 96 per cent effective as compared with habitual noncontraception. It should be noted that this statement of effectiveness is entirely different from a statement of the percentage in which the method did not fail. Table 3 gives the details of exposure, pregnancies and pregnancy rates specific by duration of marriage interval. These results are based on the experience of 542 patients, 342 having been excluded as follows: 217 for lack of follow-up on diaphragm and jelly, seventeen for possible sterility, eighty⁹ for lack of complete data, and twenty-eight for lack of exposure to the risk of pregnancy when using diaphragm and jelly.

The pregnancies recorded are the unplanned pregnancies of women who used diaphragm and jelly but who in many instances did not themselves blame the method because they relied on supplementary methods or were definitely careless. The rates¹⁰ are based on all unplanned pregnancies rather than on failures of the method for the reason that, to delete pregnancies apparently resulting from nonuse or technical errors of the patient would be justified only if there were a corresponding deduction of the exposure of patients when they took chances without becoming pregnant. Unfortunately, the latter cannot even be estimated. It is to be expected, however, that a rate based on such a selected experience would be even lower than the rate of six derived in table 3. Furthermore, any estimate of the number of unplanned pregnancies which may be called failures of the method is, at best, based on inference. Finally, one is clinically interested in the results of a method as used, and one expects the regularity and technical competence of the patient to be in part at least influenced by the acceptability of the method. Different population groups, precisely because they may be expected to employ the same method with varying regularity and skill, will probably have somewhat different rates while using it.

TABLE 3—*Months of Exposure, Unplanned Pregnancies and Unplanned Pregnancy Rates of Patients Depending Wholly or Partly on Diaphragm and Jelly, by Order of Pregnancy and by Duration of Marriage*

| Order of Pregnancy and Duration of Marriage | Months of Exposure | Number of Unplanned Pregnancies | Unplanned Pregnancies per 100 Women—Years of Exposure |
|---|--------------------|---------------------------------|---|
| All pregnancies | 15 509 | 80 | 6 |
| First pregnancies | 4 290 | 21 | 6 |
| Subsequent pregnancies | 11 219 | 59 | 6 |
| By duration of marriage interval | | | |
| 0-5.0 years | 2 617 | 21 | 10 |
| 5.1-10.0 years | 4 200 | 31 | 9 |
| 10.1-15.0 years | 3 144 | 6 | 2 |
| 15.1-20.0 years | 1 071 | 1 | 1 |
| 20.1-30.0 years | 154 | 0 | 0 |

A rough measure of the comparative effectiveness of the previous methods with the diaphragm and jelly may be obtained by contrasting the second and subsequent pregnancies for the two periods. While using diaphragm and jelly, these patients experienced fifty-nine second or subsequent pregnancies, if the chance of pregnancy had not been reduced by the diaphragm

9 The patients thus excluded had reported six unplanned pregnancies and hence had a lower relative incidence of unplanned pregnancy than the included patients.

10 The pregnancy rates are weighted mean probabilities of unplanned conception stated in terms of pregnancies per hundred woman-years of exposure.

and jelly but had continued at the previous level, there would have resulted 242 pregnancies. In other words, the chance of pregnancy was reduced about 75 per cent. Even if as many as half of the earlier pregnancies were planned, the chance of unplanned pregnancy was reduced approximately 50 per cent by diaphragm and jelly.

Patients reporting unplanned pregnancies were questioned or examined, or both, for possible explanations for their failure. Only 29 per cent of those who reported unplanned pregnancies had histories of careful use which gave no explanation for their conceptions. The conditions which may have led to conception are given in table 4. At most, forty-two of the eighty-six unplanned pregnancies might be termed failures of the method. The relative incidence of failure among the 622 users of diaphragm and jelly who have been followed up may therefore be stated as roughly 7 per cent. The value of this estimate for comparative purposes may be greatly enhanced if it is borne in mind that the average duration of exposure with diaphragm and jelly was approximately twenty-nine months, and the average length of follow-up thirty-nine months.

TABLE 4—Possible Reasons for Unplanned Pregnancies Among Users of Diaphragm and Jelly Method

| Possible Reason for Unplanned Pregnancy | Unplanned Pregnancies | |
|---|-----------------------|----------|
| | Number | Per Cent |
| Omission | 25 | 32 |
| Error in technique | 15 | 18 |
| Poor fit initially | 6 | 7 |
| Poor fit through changes in position of cervix and uterus | 3 | 3 |
| Diaphragm worn over support pessary | 1 | 1 |
| Defective diaphragm | 1 | 1 |
| Reason unknown but failed to return for check up on technique | 1 | 1 |
| No information, but failure known | 6 | 7 |
| No reason known technique satisfactory | 21 | 29 |
| Totals | 86 | 100 |

Comparisons have been made between those reporting unplanned pregnancies and the remainder of the patients in order to ascertain whether there were important differences that might explain why some patients had unplanned pregnancies while others did not. From the information available, the only important difference found was in fertility before contraceptive advice was sought. Those reporting unplanned pregnancies with diaphragm and jelly were more fertile¹¹ before their first visit as well as after. Before the contraceptive consultation their first pregnancy rate was more than twice as high (174 in comparison with 69) as that of other patients in the series, and their rate for subsequent pregnancies was 47 as compared with 30 for the remainder of the sample.

PLANNED PREGNANCY

Not the least important aspect of the control of conception is the planning of conception. In this series 131 patients have reported 167 planned pregnancies spaced by prescribed contraceptive methods. That those who planned their pregnancies were a selected group is indicated by the observation that more than 40 per cent were first seen before marriage,¹² while only 20 per cent of the nonplanners were seen before marriage. The planners also were younger, better educated and,

if married, had been married a shorter time and had experienced fewer pregnancies than the nonplanners.

Of those who were seen premaritally, three fourths conceived their first planned pregnancy within two and a half years after marriage, an additional fifth within four and a half years, and all within six and a half years. Of those who were married at the first visit but who had previously not been pregnant, one third conceived their first planned pregnancies within two and a half years after marriage, and an additional half within four and a half years.

The time required for conception was reported for 136 planned pregnancies. Fifty-one per cent were conceived within one month, 76 per cent within three months and 90 per cent within six months.¹³ When the months required for conception were summed up, the total of 400 months gave for this special form of noncontraception a pregnancy rate of 408, which is from two to four times as great as rates reported for habitual noncontraception. This rate compares with that of 446 obtained by Strix and Notestem¹⁴ with a sample roughly four times the size of the present one. The rate of 408 would be lowered to 360 by the inclusion of the five patients who had been attempting conception for from eight to fourteen months at the time of their last follow-up and who were among the seven teen possibly sterile women excluded from the computation of pregnancy rates in table 3. The indication is clear that contraceptive practice such as is discussed here does not interfere with the basic capacity to conceive. On the contrary, these patients exhibited high fertility when they ceased contraception for planned pregnancy.

SUMMARY

In twelve years contraception has become an important part of a general medical practice. The 884 white patients advised have been predominantly from upper middle class homes, of Protestant background, and college trained or the equivalent. Ninety-four per cent have been taught the diaphragm and jelly method. Analysis of the experience of the 662 patients who have been followed up indicates that:

1 The acceptance rate of the diaphragm and jelly method was 83 per cent—high enough to justify its routine prescription in private practice and low enough to illustrate the need for other prescriptions to a significant minority.

2 The chance of unplanned pregnancy, while relying wholly or partly on diaphragm and jelly, may be stated as six pregnancies per hundred woman-years of exposure for this group. This rate represents a reduction of from 93 to 96 per cent in the risk of pregnancy incurred by women habitually practicing no contraception.

3 Half of the eighty-six unplanned pregnancies followed errors or omissions that might account for conception.

4 The successful use of diaphragm and jelly did not retard conception after the method had been set aside for planned conception. The time required for conception was reported for 136 of the 167 pregnancies known to have been planned. Half were conceived within one month and three fourths within three months.

Times Medical Building, Ardmore, Pa.—2 East One Hundred and Third Street, New York.

11 This difference may reflect differences in basic fecundity in resort to contraception or in the skill and regularity with which chosen methods were practiced.

12 If the new patients of the last year are excluded and only patients first seen between 1925 and 1936 considered, one third of all those seen premaritally later reported planned pregnancies.

13 In a smaller series of sixty-eight planned pregnancies reported by patients seeking contraceptive advice, 37 per cent were conceived within one month, 77 per cent within three months and 88 per cent within six months.

RATIONAL USE OF ACACIA IN TREATMENT OF THE NEPHROTIC SYNDROME

SAMUEL A. SHELburnE, MD
DALLAS, TEXAS

The principal fault in the nephrotic syndrome is the loss of protein through damaged glomeruli. The proteins in the blood plasma decrease, so the effective osmotic pressure of the plasma is decreased and an abnormal amount of fluid escapes into the tissue, producing edema. This condition appears only after much of the body protein, such as muscles, has been depleted.¹ Hartmann² in 1933 presented a series of cases of the nephrotic syndrome in children in which he raised the effective osmotic pressure of the plasma by giving large amounts of acacia intravenously and profuse diuresis resulted. Subsequent experience has shown that if a sufficient amount of acacia is given to patients with the syndrome who have no renal insufficiency, diuresis will always occur. The effect unfortunately is only temporary, as the acacia is excreted rapidly (60 per cent in seven days). Obviously one cannot continue to inject acacia every week indefinitely, as there is reason to believe that it accumulates in the liver and the spleen³ and presumably if given over a long period might cause some ill effect.

Indeed, McCann,⁴ in his review of Bright's disease for 1936, after discussing the work of Dick,³ said "In view of such experience the further use of acacia seems unwarranted." However, critical analysis of the work of Dick and his associates will reveal that their conclusions are subject to question. They attempted to show, in children and in dogs, that acacia interferes with the production of protein. After injections of acacia they observed in both children and dogs a fall in the plasma protein content. The profound changes in blood volume associated with rapid diuresis or with the injections make estimations of the plasma protein inaccurate, even though the results of determinations of the blood volume were available, therefore it becomes clear that conclusions drawn from their experiments are of little value. If one judges by the experience of Hartmann and others, these experimenters used larger doses of acacia than were necessary. Furthermore, patients 1 and 2 of their series were entirely unsuitable for the experiments as they were clearly in the acute stage of the disease and were subject to the highly variable conditions found in that stage. Most of the patients were infants to whom it would be difficult to give a high protein diet, and without this diet the administration of acacia must be repeated indefinitely, which might eventually be harmful.

As a result of such studies and opinions, the use of this valuable asset in the management of the nephrotic syndrome has been largely abandoned. However, if acacia is used only to eliminate the edema and a diet extremely high in animal protein is instituted from the beginning, a definite increase in the plasma protein content will occur in most cases and will prevent the recurrence of edema. Repeated doses of acacia will then not be necessary.

I shall present three typical cases of chronic nephritis with the nephrotic syndrome in which acacia was an invaluable adjunct to the treatment. The edema has not returned in any of the three cases, though acacia was used only during the first few weeks and they have been observed over periods of from one to three years. I have found in each case a definite increase in plasma protein, a result contrary to previous reports. The patients were first seen as physical and psychologic invalids, and they have been returned to normal life, one is in school and the others are making good incomes. It is impossible to say how long this well being will persist. Oddly enough, patient 1 seems to be completely cured, as he has had no albuminuria during the past year. It is important to emphasize that there were no infants in this series, as it is clear that this regimen is not easily adaptable to infants. I therefore make a plea for the use of acacia to eliminate edema while the more lasting beneficial effects of a diet high in animal protein are instituted. The patients feel much better and are psychologically improved when the edema disappears.

REPORT OF CASES

CASE 1.—W. L., a Negro boy, aged 8, was admitted to Parkland Hospital Aug. 12, 1935, complaining of swelling of the face, abdomen and extremities. He had been well until May 1935, when swelling of his face associated with a severe infection of the upper respiratory tract developed. These symptoms subsided within three weeks and he was well until July 1935, when gradually increasing swelling of the face, abdomen and legs developed, he did not feel sick in any other way. He was admitted to the hospital July 15, where he remained for five days, and the edema completely disappeared. The attack was doubtless acute glomerulonephritis, as the plasma protein content was 6.6 Gm., the albumin content was 4.6 Gm. and the urine showed a 3 plus reaction for albumin, which, however, soon became negative. The patient remained well until August 1, when increasing anasarca developed.

My examination revealed that the boy was small and had edema of the legs and the face and had marked ascites. He did not appear ill. The blood pressure was 110 systolic, 70 diastolic, the pulse rate 90 and the respiratory rate 25. The tonsils were normal, the pupils reacted to light and in accommodation and the ophthalmoscopic examination gave negative results. The heart was not enlarged, and the sounds were normal, the lungs were clear. The abdomen was full of fluid, and there was edema of the scrotum and penis. The results of the laboratory examination are shown in table 1. The outstanding observations were persistent albuminuria, a normal blood urea content, a blood cholesterol content of 220 mg. and a plasma protein content of 5 Gm. The Mosenthal test was negative, and there was no anemia. The Wassermann and the Kahn reaction were negative. An intravenous pyelogram showed nothing significant. The diagnosis was chronic nephritis with the nephrotic syndrome.

The patient was confined to bed on admission and given a high protein, low salt diet. He was given many diuretics including theobromine, caffeine, ammonium nitrate and salyrgan with no effect. He was also given from 1 to 3 grains (0.06 to 0.2 Gm.) of thyroid extract daily for a prolonged period. The edema increased as shown by a rise in weight from 63 pounds (28.6 Kg.) on admission to 76 pounds (34.5 Kg.) on November 27, the day the first dose of acacia was given. At

¹ After the manuscript of this paper had been submitted several papers of great importance appeared. Both M. J. Lepore (Acacia Therapy in Nephrotic Edema *Ann Int Med* 10: 285 [Aug.] 1937) and E. M. Landis (Observations on Acacia Therapy in Nephrosis *J A M A* 109: 2030 [Dec. 18] 1937) point out the great efficacy of acacia in removing this type of edema and the harmlessness of the product. Neither of these studies stressed the principal thesis of my paper, i. e. the temporary use of acacia for diuresis and the dependence on high protein diet for permanent effects. Landis (personal communication) reports one failure in a recent case, which he is unable to explain. Heckel (Blood Plasma Proteins as Influenced by Intravenous Injections of Gum Acacia *J Exper Med* 67: 345 [March] 1938) shows beyond doubt the ill effect of the continued use of acacia. The continuous use of acacia should be avoided even if edema returns.

this time the patient's condition was regarded as a hopeless problem and he was referred from the pediatric department to my service, with little hope that anything of value could be done. I felt that the trial of acacia provided a discouraging outlook, as the reports at that time were none too optimistic. The patient had had several abdominal paracenteses, and the fluid reaccumulated rapidly. He had had three large blood transfusions without the slightest effect on the urinary output. It might be worth while at this point to add that I have never had any beneficial results from blood transfusions.

The patient was given 100 cc of acacia solution (30 Gm, Lilly) in 200 cc of water on November 27, with no change in weight the following day. This dose was repeated on November 29. The next day his weight was 69 pounds (31 Kg), and three days later, when he was given another similar dose, it was down to 65 pounds (29.5 Kg). It had fallen to 57 pounds (26 Kg) on December 6. When a fourth dose was administered on December 9, the patient weighed 52½ pounds (24 Kg) and had no trace of edema. There was a total loss of weight of 24 pounds (11 Kg) within thirteen days, representing 31 per cent of the total body weight.

CASE 2—J. W. H., an adult man, who was referred to me by Dr. H. A. O'Brien of Dallas, Texas, on Feb. 12, 1936, complained of extreme swelling of the legs and abdomen, great exhaustion and loss of flesh. The loss of flesh was most noticeable in the upper extremities, doubtless because of the edema elsewhere. He stated that he had been well until June 1935, when he began to have exhaustion, which increased until the edema appeared in July. An examination of the urine at this time showed a 4 plus reaction for albumin and a few red blood cells and casts. A diagnosis of chronic nephritis was made, and the patient was treated with rest, a low protein diet and extraction of his teeth. He did not improve with this program, and he was admitted to a hospital in Temple, Texas, in November 1935. It was found that he was excreting from 8 to 15 Gm of albumin per day. The serum protein content was 5.4 Gm per hundred cubic centimeters, and the urine was normal except for albumin and an occasional red blood cell. The blood urea content was 25 mg per hundred cubic centimeters. The phenolsulfonphthalein excretion was 53 per cent, the electrocardiogram was normal, the basal metabolic rate was minus 19 and the Wassermann and Kahn reactions were negative.

The patient remained well going to school and playing actively, until Feb. 15, 1936, when ascites began to return. He was admitted to the hospital on March 2 for observation. At that time his weight was 56 pounds (25.4 Kg). Examination gave negative results except that it showed a small amount of fluid in the abdomen. The laboratory studies showed nothing abnormal except albumin in the urine, mild secondary anemia and a low plasma protein content. The cholesterol content at this time was 100 mg. The patient was given a high protein diet and the ascites promptly disappeared. This recurrence was doubtless due to failure of the parents to supply him with the high protein diet.

After the patient's discharge in March 1936 we had great difficulty in observing him, as he was so well the family refused to bring him in. Finally, a year later, on March 19, 1937, he came into the clinic. The urine at that time had a specific gravity of 1.025, a 1 plus reaction for albumin and a 3 plus reaction for white blood cells. We could not determine the origin of the pus in the urine, but a later examination gave negative results throughout. The blood count was normal, the plasma protein content 7.6 Gm, the albumin content 4.3 Gm and the globulin content 3.3 Gm.

Roentgenograms of the gastro-intestinal tract and of the kidney, ureter and bladder showed nothing abnormal. Examination of the nose and throat showed a heavy secretion in the nose, a deflected septum and infected tonsils.

The patient was advised to eat a normal diet, but no other direct treatment was suggested. He continued to have extreme edema and exhaustion and was unable to go about his regular duties. He was under the care of a local physician during this period. This physician gave him a number of injections of salyrgan, which provided temporary diuresis, with rapid return of the edema. He was also treated with thyroid and received one transfusion, with little or no effect.

My examination showed that the patient was well developed, with a large frame. Muscular atrophy was present, which could be seen best in the shoulder girdle, as there was extensive edema of the legs and marked ascites. Some edema was present in the eyelids. The remainder of the examination showed nothing abnormal except a tender prostate, fluid from which showed some pus. A laboratory examination was performed in the hospital, and the results are reported in table 2. The outstanding observations were a low plasma protein content, a normal cholesterol content, a large daily output of albumin in

the urine and a normal urea nitrogen content and excretion of phenolsulfonphthalein. The diagnosis was chronic nephritis with the nephrotic syndrome.

The patient was immediately placed on a high protein diet and given a large beefsteak every night. He has remained on this diet since that time. He was given 100 cc of a 30 per cent acacia solution in 400 cc of water on February 14. Two days later he received 200 cc of the same solution, and on the eighteenth he had lost 6 pounds (2.7 Kg), his weight having dropped from 187 to 181 pounds (85 to 82 Kg). He received 200 cc of acacia solution on February 20 and a similar amount on March 10. On March 13 he weighed 171 pounds (77.6 Kg), a total loss of 16 pounds (7.3 Kg), having taken place. It is interesting to note that the loss of weight was gradual during this month of treatment. The patient's condition was greatly improved, he was able to return to work, and he has since been working constantly, living on a regimen no different from that of the average person, except that he eats a large thick steak every night and high protein foods at the other meals. It is interesting to note that he has shown a definite and persistent increase in the plasma protein content, as shown in the table, since he has been on the high protein diet.

CASE 3—E. V., a white man, aged 20, had been perfectly well until January 1936, when, without any prodromal symptoms, a gradually increasing swelling of his entire body, including the face, developed. He then began to have moderate shortness of breath. This symptom was not present before

he was given an additional 200 cc of acacia and had a severe reaction, with chill and vascular collapse, but recovered within six hours. This was the first and only reaction of any severity which we observed, and it was due to negligence.

The patient was sent home on August 3 but failed to follow his high protein diet closely and had to receive 150 Gm of acacia from his local physician. He has since been careful to eat the large steaks, and the administration of acacia has not had to be repeated. I made a complete examination of him on March 17, 1937, and found no edema, but he was excreting large quantities of albumin daily (maximum, 12 Gm). However, the serum protein content had increased from 3.1 Gm to 5.6 Gm per hundred cubic centimeters. The urea nitrogen content was 18 mg and the phenolsulfonphthalein excretion 89 per cent. The urine contained few red cells and no casts. The patient was feeling fine and had been working hard for the past year. He was reexamined on Sept. 14, 1937, and appeared perfectly well. His muscles had developed magnificently, but he was still excreting large amounts of albumin. The serum protein content was 3.7 Gm. He was working full time and felt well.

COMMENT

One might properly ask why acacia should be used in the treatment of the nephrotic syndrome if the lasting benefits are derived wholly from the use of a high protein diet. In the first place, the high protein diet alone will rarely raise the level of plasma proteins fast

TABLE 3—Progress in Case 3

| Date | Weight Pounds | Edema | Plasma Protein Gm * | Blood Urea Nitrogen Mg | Blood Cholesterol, Mg | Hemoglobin, Percentage | Urine Protein, Gm | Acacia Gm | Comment |

the onset of the edema and was not marked thereafter. He remained in bed for one month and the edema disappeared, but it recurred when he got up and about again. He was studied in a hospital in Temple, Texas, and a diagnosis of chronic nephritis was made. He was placed on a low salt and low protein diet, with no benefit. The swelling persisted until I saw him on July 15, 1936, but he had no other symptoms except weakness and cramping of his arms and legs. He was unable to work because of the weakness and the edema.

At examination he looked healthy and well nourished but had marked edema below the knees. The retina was entirely normal, the throat was particularly clean, the teeth were normal, the lungs were clear, the heart was not enlarged and the sounds were normal. The blood pressure was 138 systolic, 82 diastolic. There was some ascites. The examination, otherwise gave negative results. The results of laboratory study are shown in table 3. The outstanding observations were the extremely low serum protein content, 3.1 Gm per hundred cubic centimeters, normal nitrogen and cholesterol levels and a large amount of albumin in the urine, with very few red cells and no casts. The diagnosis was chronic nephritis with the nephrotic syndrome.

The patient was placed on the usual high protein diet and given a large steak each night. An interesting point in this case is the fact that he did not follow directions at first in regard to the size of his steak and had to have the administration of acacia repeated after the preliminary period. However, since that time he has followed directions closely and has had no recurrence of edema. He was given 200 cc of 30 per cent acacia solution July 17, and this dose was repeated on July 19, and again on July 23. He was also given 100 cc on July 25. On July 29 he had lost all his edema, his weight having gone down from 150 to 136 pounds (68 to 62 Kg). By an error,

enough to eliminate the edema. This is doubtless because the patients have to take the diet over a long period and are discouraged before results can be attained. By using acacia one can in every case eliminate the edema within a few days. The patient is greatly encouraged by this dramatic effect, his confidence is restored and his psychologic improvement is enormous. He is not so obviously a sick man and is able to resume contact with the public. The relief from the edema increases his comfort, as he has suffered with a tight feeling in his abdomen and his feet and usually has had dyspnea. The removal of the fluid completely eliminates the danger of peritonitis, which is such a dreaded complication. The tissue nutrition should be improved by the elimination of the edema fluid.

The limitations of the use of acacia are too many to mention here, though it is important to note that its use is not worth while when the edema associated with chronic nephritis is due to cardiac failure or to capillary damage. It is not useful in the treatment of starvation edema, as this type of edema can quickly be corrected by the eating of protein food. It should not be used in the management of acute forms of nephritis, as the associated edema is practically always due to damaged capillaries and not to a low plasma protein content. Furthermore, the tendency to cure in such cases is so great that acacia therapy is not necessary. Its usefulness in the treatment of infants is problematic. Doubtless it will relieve edema due to a low plasma

protein content, but, since the infant cannot be given a sufficiently high protein diet, the benefits are not lasting

SUMMARY

The advantage of acacia therapy in the management of chronic nephritis with the nephrotic syndrome was demonstrated in three cases. An important point is that the acacia was used only as a temporary measure for the elimination of edema in the very beginning and that the principal therapeutic measure is the use of a diet high in animal protein.

THE RATIONALE OF SULFANILAMIDE IN GONOCOCCIC URETHRITIS

JAMES I. FARRELL, M.D., PH.D.

EVANSTON, ILL.

YALE LYMAN, M.B.

AND

G. P. LOUMAN, PH.D.

CHICAGO

No therapeutic agent used in the treatment of gonorrhea has caused as much comment as sulfanilamide. One may read of its use in lay and medical periodicals. As yet, no experimental work has been advanced to explain its action in urethral infections. The experiments reported here were conducted in our laboratory to find out how the drug acts on genito-urinary infections.

Reuter¹ reports 100 cases of gonorrhea in which treatment with sulfanilamide was given by mouth. There were approximately sixty cases of chronic infection and forty of acute anterior urethritis. About 90 per cent of these cases were reported as cured, none of them showed any complications. Dees and Colston² report nineteen cases of gonorrhea in various stages in which treatment was with sulfanilamide. They report about 90 per cent of their patients cured. Likewise, no complications were noted, and the following comment is made: "It has been especially impressive to us that the infection in none of our treated cases has progressed from anterior to posterior urethritis or from anterior urethritis to prostatitis or epididymitis after the institution of the treatment."

One of us (Farrell) has treated ten cases of gonorrheal urethritis with sulfanilamide by mouth. Only five of the patients responded to treatment. The other five seemed to derive little benefit from the drug, as evidenced by persistent discharge, so that local treatment was begun. None of the ten patients had any complications such as posterior urethritis, prostatitis or epididymitis. Because of the repeated observations by the various observers that no complications occur, it seemed advisable to us to determine a rational basis for the use of sulfanilamide in gonorrhea. Marshall³ has shown that sulfanilamide is rapidly absorbed from the gastro-intestinal tract and enters practically all fluids of the body and that it is excreted almost entirely

through the kidneys, from 70 to 93 per cent being excreted in twenty-four hours. Marshall also reports that it usually takes from two to three days to establish an equilibrium between intake and output. In the dog the normal excretion occurs about four hours after the ingestion of the drug. He found that from 11 to 16 mg. of sulfanilamide is present in 100 cc. of blood in the treated dog.

Buttle, Colebrook and O'Meara⁴ have shown that sulfanilamide is active in vivo in from 1,000 to 13,000 parts in the blood against streptococci. Control specimens of blood showed an increased growth of streptococci.

Helmholz⁵ has shown that the urine of patients taking sulfanilamide by mouth is strongly bactericidal against the organisms usually found in infections of the urinary tract. The drug appeared to be more active in alkaline urine.

EXPERIMENTAL DATA

Large male dogs were used in our experiments. The dogs were given sulfanilamide by mouth for several days, the daily dose being approximately 0.18 Gm. per kilogram. The dogs were anesthetized with pentobarbital sodium given intravenously. In order to collect the secretion from the posterior urethra, the urethra was tied off at the bladder opening and a cannula placed in the portion just distal to the prostate gland. Thus we were able to collect the prostatic secretion and also the secretion of the glands of the posterior urethra uncontaminated with urine or blood. In addition, samples of blood and urine were collected from each dog. The content of sulfanilamide in these specimens was determined by the method described by Marshall. The results are given in table 1.

TABLE 1—Content of Sulfanilamide in Blood, Prostatic Secretion and Urine

| Dog | Dosage of Sulfanilamide | Mg. of Sulfanilamide in 100 Cc. | | |
|-----|-------------------------|---------------------------------|---------------------|-------|
| | | Blood | Prostatic Secretion | Urine |
| 1 | 10 grains 3 times a day | 7.6 | 3.8 | 3.2 |
| 2 | 10 grains 3 times a day | 3.7 | 3.4 | 2.1 |
| 3 | 10 grains 4 times a day | 16.6 | 13.2 | 11.3 |
| 4 | 10 grains 4 times a day | 17.3 | 13.1 | 14.0 |

TABLE 2—Effect of Prostatic Secretion on Staphylococci and Colon Bacilli

| | Colon Bacilli | | | | Staphylococci | | | |
|----------------------------------|---------------|--------|--------|---------|---------------|--------|--------|---------|
| | 0 | 2 Hrs. | 4 Hrs. | 24 Hrs. | 0 | 2 Hrs. | 4 Hrs. | 24 Hrs. |
| Dog 1 normal prostatic secretion | In | 672 | 96 | 0 | In | In | 10 | 40 |
| Dog 2 after sulfanilamide | In | 104 | 0 | 0 | In | In | 64 | 28 |
| Dog 3 normal prostatic secretion | In | In | 90 | 0 | In | In | 80 | 0 |
| Dog 4 after sulfanilamide | In | 472 | 108 | 0 | In | In | 160 | 8 |

In means Innumerable

The first two dogs were operated on several hours after their last dose of sulfanilamide was given. Dogs 3 and 4 were operated on between the third and fourth hour after their last dose of sulfanilamide. The concentration of the sulfanilamide in the secretion obtained from the prostatic urethra is slightly greater than the concentration in the urine.

⁵ Helmholz, H. F. Bactericidal Power of Urine After Administration of Prontosil by Mouth. *Proc. Staff Meet. Mayo Clin.* 12: 24-25 (April 21) 1937.

After recovering the drug in the urine and prostatic secretion in such concentrations, we sent the specimens to the bacteriology laboratory, where they were tested against the strains of staphylococci and colon bacilli. Gonococci were not used because of their extreme susceptibility to change in various mediums and temperatures, it being thought best to try the bactericidal action against the more common organisms.

Table 2 shows the effect of prostatic secretion both from normal dogs and from dogs given sulfanilamide, on staphylococci and on colon bacilli.

TABLE 3—*Germicidal Activity of Sulfanilamide on Prostatic Fluid*

| Sample | Organisms | Number of Colonies Time of Plating in | | | |
|------------------|--------------|--|-------|------|--------|
| | | 0 | 2 Hrs | 4 Hr | 24 Hrs |
| 1 Normal | Coli | In | In | 6 | 0 |
| Sulfanilamide | Coli | In | In | 2 | 0 |
| H ₂ O | Coli | In | In | In | In |
| 2 Normal | Coli | In | 240 | 765 | 48 |
| Sulfanilamide | Coli | In | 70 | 10 | 0 |
| H ₂ O | Coli | In | In | In | In |
| Normal | Staph aureus | In | In | In | 75 |
| Sulfanilamide | Staph aureus | In | In | In | 0 |
| H ₂ O | Staph aureus | In | In | In | In |

In order to determine whether the drug was effective when given intravenously and at the same time have a control prostatic secretion from the same dog two animals were anesthetized and the prostatic secretion was collected. One and five-tenths grams of sulfanilamide dissolved in 200 cc of physiologic solution of sodium chloride was given intravenously, the prostatic secretion was then collected for a period of two hours. The results are recorded in table 3.

METHODS

The prostatic fluid was tubed aseptically in 1 cc amounts in sterile Wasseimann tubes. The tubes together with a control tube of sterile distilled water were inoculated with one standard 4 mm loopful of a twenty-four hour meat infusion broth culture of either *Staphylococcus aureus* or *B. coli*. The tubes were then placed in the incubator at 37 C and agar plate subcultures made immediately, at two four and twenty-four hour intervals by transferring one standard loopful to a tube of melted and partially cooled meat infusion agar. The plates were incubated at 37 C for forty-eight hours and examined to determine the number of colonies present. Actual counts were made when possible, otherwise the number of colonies was recorded as innumerable innumerable plus or innumerable minus, or compared with the control.

RESULTS

The prostatic fluid of two dogs which had received sulfanilamide intravenously after a sample of normal prostatic fluid had been obtained was tested for germicidal activity. Both samples were tested with *B. coli* and only one with *Staphylococcus aureus*, as shown in table 3.

The sulfanilamide is excreted in bactericidal concentrations, in both the urine and the secretion of the posterior urethra, when adequate doses are given. According to our experiments from 10 to 15 mg of sulfanilamide seems to be adequate antiseptic concentration. The experiments demonstrate that the bactericidal power of prostatic secretion on colon bacilli and *Staphylococcus aureus* is marked. In twenty-four hours

all the bacteria were reduced in number. In dogs given sulfanilamide in approximately human doses, there were no viable bacteria on the plate at the end of twenty-four hours.

COMMENT

The foregoing experiments give one a logical explanation of the action of sulfanilamide in the genito-urinary tract. When the kidney is normal the drug is excreted in concentrations that are bactericidal. This means that the lower genito-urinary tract is continually in contact with a strongly bactericidal urine. The secretions of the posterior urethra, notably the secretion of the prostate gland, have a similar effect. The drug content in this secretion prevents the spread of gonococci into the posterior urethra. It is a well recognized clinical fact that a posterior urethritis is the forerunner of the serious complications of gonorrhea such as prostatitis, epididymitis and arthritis. The infection of the posterior urethra is effectually prevented by the excretion of sulfanilamide in the prostatic secretion and thus effectually confines the urethritis to the anterior urethra.

SUMMARY

Sulfanilamide, when given in adequate amounts is secreted in the urine and prostatic secretion in bactericidal concentration. When the drug was given in smaller amounts it did not appear to be as effective as when administered in larger amounts.

The drug appears to act directly on the infecting organisms in the urinary tract.

636 Church Street

THE SUCTION TEST FOR CAPILLARY RESISTANCE IN THROMBOCYTOPENIC PURPURA

R. H. EGERTON ELLIOTT, M.D.

NEW YORK

It has long been recognized that a state of lowered capillary resistance exists in patients with thrombocytopenic purpura. It has furthermore been recognized that the degree of lessened resistance is in general proportional to the severity of the disease process. Therefore a determination of the state of resistance of the capillaries is generally included among the measures employed to ascertain the presence and the activity of the disease. The three principal methods which have been used in this determination are (1) the tourniquet test, (2) the intradermal venom test and (3) the suction test.

The tourniquet test was introduced as a method of measuring capillary resistance in 1911 by Weill, Rumpel, Leed and others. Despite the recent introduction of qualitative¹ and quantitative² modifications this type of determination leaves much to be desired, as it is both cumbersome and time consuming. Furthermore, it is poorly adapted to measuring the degree and the rapidity of the fluctuations in capillary resistance which may occur in patients with purpura.

From the Department of Surgery, Columbia University College of Physicians and Surgeons and the Spleen Clinic of the Presbyterian Hospital.

¹ Jones H. W. and Tocantins L. M. A Simple Test for Capillary Resistance. The Flicking Test. *Am J M Sc* 185: 535 (April) 1933.

² Gothlin C. F. A Method of Establishing the Vitamin C Standard and Requirements of Physically Healthy Individuals by Testing the Strength of Their Cutaneous Capillaries. *Scandinav Arch f Physiol* 61: 225 (May) 1931.

The intradermal venom test was first described by Peck³ in 1936. I have had little experience with it, but it would seem likewise to have the disadvantage of being of little assistance in following the daily course of the severity of the disease as reflected by the resistance of the capillaries.

The suction method of measuring capillary resistance is by no means new. First described by Hecht in 1907

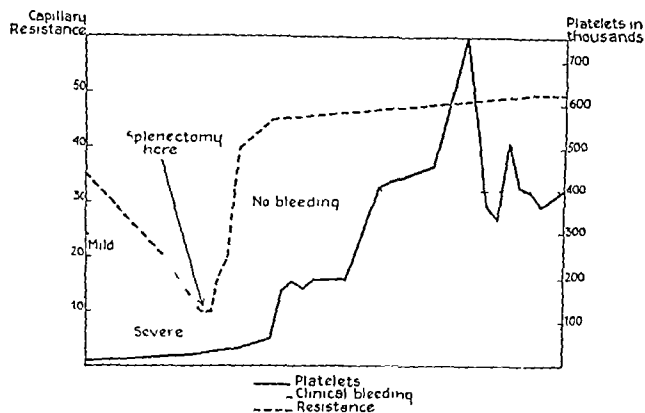

Chart 1—Clinical course in a case of idiopathic thrombocytopenic purpura haemorrhagica in which the spleen was removed twelve days after admission because of failure of conservative therapeutic measures. In the charts the solid line indicates platelets, the broken line capillary resistance and the dotted line bleeding.

and only recently popularized by da Silva Mello abroad and Dalldorf in this country, it has been used principally in cases of scurvy. Strangely enough, though there are abundant references in the recent literature to its use in the treatment of that condition and though it is undoubtedly being widely used in cases of the hemorrhagic diatheses, we were able to find only four brief accounts of its use in the treatment of purpura. Bruhl⁴ described its use in a case of idiopathic thrombocytopenic purpura but said little about the method itself. Brock and Marcus,⁵ in discussing its use in the treatment of various hemorrhagic conditions, cited Bruhl's case and briefly mentioned one of their own in which it was used. Falconer, Epstein and Weaver⁶ mentioned its use in two cases of purpura following neosarsphenamine therapy, and Peck, Rosenthal and Erf⁷ in their recent article on purpura described the histopathology of the petechiae produced in patients with that condition by its use.

Of the three aforementioned methods of determining capillary resistance, the suction test has appealed to my co-workers and me as the most desirable by virtue of its simplicity, relative accuracy and rapidity of operation. Of even more importance is the fact that it seems to be the best available method for measuring the daily or hourly fluctuations in resistance so often encountered in patients with thrombocytopenic purpura. During the past two years therefore its use on all patients with purpura treated in the Spleen Clinic of the Presbyterian Hospital has become a matter of routine.

⁷ Peck S. M., Rosenthal Nathan and Erf Lowell. Purpura Classification and Treatment with Special Reference to Treatment with Snake Venom. *Arch. Dermat. & Syph.* 35: 831 (May) 1937.

Using the Dalldorf modification of the da Silva Mello instrument,⁸ our procedure has been to apply suction to the forearm about 2 cm distal to the antecubital fossa. A given negative pressure is maintained for one minute and a reading taken. The lowest negative pressure giving a positive reaction is considered to be the capillary resistance. For a reading to be positive a minimum of two petechiae must be clearly discernible.

The method, as has been pointed out by Dalldorf and others, is by no means absolutely accurate, for too many variables, such as thickness, texture and color of the skin and varying intensities of light, are present. For this reason we do not attempt to measure resistance values below minus 10 cm of mercury or above minus 50. We do feel, however, that the test gives a reasonably accurate estimate of the state and change of capillary resistance when performed on a given area of skin and, when possible, by a single observer.

NORMAL VALUES

In general our 'normal' values for capillary resistance measured just below the antecubital fossa with the Dalldorf apparatus agree closely with those of other observers. The majority of healthy adults whom we have tested have given values falling within the range of from minus 20 to minus 35 cm of mercury. In the presence of suspected or proved ill health values below minus 20 have been considered abnormal.

CLINICAL MATERIAL

As has been stated previously, determinations of the capillary resistance are performed as a matter of routine at each visit of all patients with purpura who attend the Spleen Clinic of the Presbyterian Hospital. In all, some thirty-five persons with purpura, not to mention numerous persons with various other types of blood dyscrasias, are being so observed.

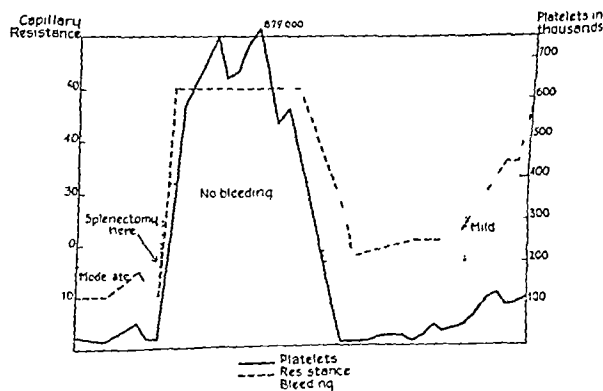

Chart 2—Clinical course in a case of idiopathic thrombocytopenic purpura haemorrhagica in which splenectomy was performed three weeks after admission because a conservative regimen did not give improvement.

It has been our experience that in each case the values for capillary resistance tend to parallel closely the bleeding tendency, low values being present in the active phases of the disease and higher, or normal values in the inactive phases. Furthermore, we have found this to be true irrespective of the level of the platelet count. In other words when, as occasionally happens, the bleeding tendency is active in the presence

⁸ Dalldorf Gilbert. A Sensitive Test for Subclinical Scurvy. *N. Y. J. Med.* 46: 794 (Oct.) 1933.

of a normal platelet count or when the tendency is inactive in the presence of thrombocytopenia, the resistance values tend to parallel the former rather than the latter

In addition, after splenectomy the capillary resistance may be the first measurable entity to be quantitatively affected (chart 1). In seven recent cases of so-called idiopathic thrombocytopenic purpura in which splenectomy was performed, the resistance values rose from 5 to 40 cm of mercury within the first twenty-four hours after operation (charts 1 and 2). In one case the resistance rose from a preoperative level of minus 10 to minus 20 after the spleen had been removed but before closure of the abdominal wound had been completed. From the first two charts it will be seen further that immediately after splenectomy and at the time resistance rose all clinical bleeding ceased. It is also

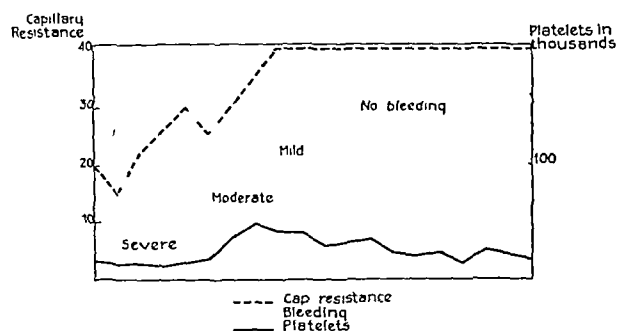

Chart 3—Clinical course in a case of thrombocytopenic purpura following the administration of pneumococcus antiserum for type I lobar pneumonia. The onset of purpura took place eight days after the first injection of antiserum. Complete cessation of bleeding manifestations occurred nine days later and the patient was discharged in good health nineteen days after the onset of hemorrhagic symptoms.

of interest that the elevation of the platelet count following operation may lag behind the rise in resistance (chart 1).

Chart 3 depicts the parallelism between the clinical bleeding and the capillary resistance in a person with symptomatic purpura and, in addition, clearly shows the discrepancy which may exist between the platelet level on the one hand and the bleeding tendency and the capillary resistance on the other.

SUMMARY AND CONCLUSIONS

The suction method of measuring capillary resistance is a simple, relatively accurate means of following the frequent fluctuations in the permeability of the capillaries in patients with thrombocytopenic purpura.

The capillary resistance in thrombocytopenic purpura tends to parallel the bleeding tendency rather than the platelet level.

The suction method of measuring capillary resistance is a useful means of estimating the activity of the disease process in patients with thrombocytopenic purpura and may, in certain instances, be of more value in this connection than the platelet count.

In seven cases of idiopathic thrombocytopenic purpura, the capillary resistance rose abruptly during the first twenty-four hours after removal of the spleen and in one instance doubled the preoperative level before closure of the abdominal wound had been completed.

After splenectomy for idiopathic thrombocytopenic purpura, the capillary resistance may be the first measurable entity to be materially affected, the rise in resistance preceding that of the platelets.

THE INTERPRETATION OF EXCESSIVE GONADOTROPIC HORMONES

EXCRETED IN THE URINE IN EARLY PREGNANCY

A. J. KOBAK, M.D.

CHICAGO

It has been demonstrated that large quantities of gonadotropic hormones are excreted into the urine when chorionepithelioma or hydatidiform mole is present. It has been shown that up to 50 per cent of the chorionepitheliomas studied have been preceded by hydatidiform moles. It would be advantageous therefore if a diagnosis could be made early by testing the urine for these hormones. It has been contended that if a diagnosis was made before full clinical signs developed, complete eradication of the tumor could be carried out before metastasis occurred. The reports of Leventhal and Saphir,¹ Mathieu and Palmer,² Kimbrough³ and Garber and Young⁴ have shown this.

REPORT OF CASE

C. E. S., a white woman, aged 32, a primipara, secundigravida, last menstruated Dec. 30, 1934. Her first pregnancy was terminated by a low forceps delivery after a slight hemorrhage, which was due to a marginal placenta praevia. The second pregnancy was uneventful until June 30, 1935, or about the twenty-sixth week, when it was noted that she was losing weight and had never felt any fetal movements. Examination showed absence of the fetal heart tones, and as the height of the uterus corresponded to that of a twenty weeks pregnancy a diagnosis of missed abortion was made. On July 8 the patient had a profuse hemorrhage, and in a few hours she expelled a hydatidiform mole. Examination disclosed three small fibroid nodules on the posterior wall of the uterus. The uterine cavity was curetted, and the patient made an uneventful recovery and left the hospital in four days. August 7 a Friedman test was negative.

The patient was again seen September 14, at which time the uterus was soft and enlarged, corresponding to the size of a six weeks pregnancy. The patient stated that she had cohabited but once. A condom was used for contraception at that time, which was six weeks prior to this examination and less than one month after the curettage. The Friedman test was now found to be positive. The patient was seen one week later, September 21, and reported that she had had a profuse painless vaginal hemorrhage which had lasted for two hours before stopping spontaneously. The size of the uterus at this time was found to correspond to that of an eight to ten weeks pregnancy. A quantitative determination of the gonadotropic hormones in the urine was made by a slight modification of the original Aschheim-Zondek method (technic described by Leventhal and Saphir¹). The tests showed that a minimal concentration of the hormone content was estimated to be 150,000 mouse units per liter. In reporting this test Dr. William Saphir stated that there was a great likelihood of the presence of a chorionepithelioma.

The diagnosis was obscured by the contraceptive precaution. Furthermore, the possibility of a pregnancy occurring within four weeks from the date of the curettage was unlikely. With the uterus growing rapidly for one week the hemorrhage and the hormone observations, the diagnosis of uterine pregnancy became even more dubious. September 28 the patient was admitted to the Michael Reese Hospital where the uterus was emptied by an abdominal hysterotomy. It contained a normal fetus and placenta about 10 weeks of age. The left

ovary contained a normal corpus luteum of pregnancy. The fibroids were removed and the patient made an uneventful recovery. Microscopic examination of the placenta showed nothing abnormal. Two subsequent Friedman tests were negative.

COMMENT

This case demonstrates the difficulty in diagnosis when, after the expulsion of a hydatid mole an unexpected pregnancy intervenes. According to Zondek⁵ "Production of gonadotropic principle is greatest at the beginning and in the early months of pregnancy, it diminishes in the latter months (Aschheim and Bernhard Zondek). In early pregnancy the content of this substance amounts to an average of 10,000 mouse units per liter of blood and from 5,000 to 30,000 mouse units per liter of morning urine."

Evans and his associates⁶ have recently demonstrated that in the early months of pregnancy the anterior pituitary-like hormones in the urine may reach a high peak. This peak, which is regarded as a normal phenomenon appeared invariably one month from the beginning of the first expected but missed menstruation. Its level may equal that found in hydatidiform moles and chorionepithelioma. With hyperemesis gravidarum⁷ and with toxemias of late pregnancy⁸ there is likewise an abnormally large quantity of these substances in the urine.

Reeb, Nerson and Klein⁹ reported two cases in which they were erroneously led to believe that they were dealing with hydatidiform moles because of repeated hemorrhages together with a high level of gonadotropic hormones in the urine. When more negative reports, such as this are made, the diagnostic value of large quantities of gonadotropic hormones in the urine will be more limited.

Cases have been reported in which the hormone content was either negative or present in ordinary quantities, although hydatidiform mole or chorionepithelioma was present in the uterus (Fluhmann,¹⁰ and Cion in discussing Gough's paper¹¹). Laboratory test of the hormone content should therefore be interpreted cautiously before a diagnosis is made. The clinical history and physical appearances should be given primary consideration before one concludes that chorionepithelioma or hydatidiform mole is present.

CONCLUSION

The presence of urinary gonadotropic hormones in high concentrations necessitates the definite exclusion of a normal pregnancy before the diagnosis of hydatidiform mole or chorionepithelioma is considered.

Conclusive Clinical Proof—Admittedly conclusive clinical evidence is hard to come by, since controls are seldom possible, but we are too apt to accept such evidence as is pleasing to our prejudices. That is the basis common to both these prevalent weaknesses—obstinate conservatism on the one hand, credulity on the other. If a new idea can be fitted into the authoritarian framework we are too apt to accept it uncritically, whereas if it breaks new ground we are too likely to reject it.—Langdon-Brown, Walter. *The Dead Hand in Medical Science, Lancet* 1: 279 (Jan 29) 1938.

Clinical Notes, Suggestions and New Instruments

ORTHOSTATIC HYPOTENSION. REPORT OF A CASE TREATED WITH NEOSYMPHRIN HYDROCHLORIDE

GEORGE D. CAPACCIO, M.D. AND CHARLES J. DONALD, M.D.
SEATTLE

Orthostatic hypotension as an entity has been brought to the attention of the clinician chiefly since the report of Bradbury and Eggleston¹ in 1925. The condition is thought to be the result of dysfunction of the autonomic nervous system. There is loss of reflex vasoconstriction and reflex acceleration of the cardiac rate, usually associated with the assumption of the erect position. It is characterized chiefly by inability to maintain a blood pressure consistent with normal activity when erect. After the patient assumes the erect position there is a decided drop in both systolic and diastolic blood pressure with the production of marked weakness or actual syncope. There is associated failure of reflex cardiac acceleration and often deficient sweating. Chew, Allen and Barker,² in a recent report of six cases, enumerate additional signs and symptoms as (1) accentuation of symptoms in hot weather, (2) excretion of larger amounts of urine when recumbent, (3) appearance of youthfulness, (4) lowered basal metabolism, (5) evidence of organic change in the central nervous system, (6) loss of sexual desire, (7) pallor of the skin and (8) elevation of the blood urea to the upper limits of normal.

The following is the report of a case that has responded satisfactorily to the oral administration of neosynphrin hydrochloride.

History—A white woman, aged 56, had always enjoyed good health. In 1932, five years prior to admission, she experienced an attack of colitis, from which she recovered uneventfully. In 1933 she first noticed weakness, blurring of vision and vertigo on assuming an erect position. This gradually became worse to such a degree that in 1934 she experienced weakness, vertigo and actual syncope on standing. Consciousness was regained about one to one and a half minutes after recumbency and no ill effects were noted. There had always been an associated hypohidrosis more noticeable since 1932. In the fall of 1936 she became materially worse, and several months prior to admission she had been placed on a regimen that included adrenal cortex extract, digitalis and thyroid extract, with no material benefit. During these years weakness, blurring of vision and vertigo occurred constantly when the patient was standing up and for only short periods of time was there freedom from syncope. She learned to walk with the shoulders stooped forward, and on feeling faint she would automatically lower her head without stopping and would feel considerably better. Just prior to admission in April 1937, she had recovered from several attacks of nausea and vomiting, entailing a loss of weight of about 16 pounds (7.3 Kg.).

Examination—The patient was dark complexioned and well preserved. She appeared chronically tired and to be her stated age. The eyes, nose, throat, teeth, ears and neck were not remarkable. Examination of the heart gave no significant results. The blood pressure was as follows: recumbent 124 systolic, 82 diastolic, sitting 52 systolic, 36 diastolic and unobtainable, with syncope, on standing. There was an immediate return of consciousness with recumbency. The peripheral vessels were not remarkable. The lungs were clear and the remainder of the physical examination, including a neurologic survey, showed no manifestations of significance.

Examination of the blood revealed hemoglobin 105 per cent, 144 Gm. erythrocytes, 5,090,000 leukocytes, 8,800 differential.

From the Ma on Clinic, Frederick Stearns & Co. supplied the neosynphrin hydrochloride for clinical trial.

count normal The urine was negative except for a slight amount of pus The Wassermann and Kahn reactions were negative

A diagnosis of orthostatic hypotension was made and efforts were directed toward determining its nature, whether primary or secondary Further laboratory studies were as follows Blood urea nitrogen was 14 mg, nonprotein nitrogen 51 mg per hundred cubic centimeters The icterus index was 6, the blood chlorides 495 mg per hundred cubic centimeters, serum protein 6.66 Gm, serum albumin 4.49 Gm A dextrose tolerance test showed the blood sugar to be 111 mg per hundred cubic centimeters fasting, 117 mg at the end of one hour, 90 mg at the end of two hours, and 76 mg at the end of three hours, urine sugar being 0 on all tests The basal metabolic rate was minus 18 A Mantoux test was 1+

TABLE 1—Blood Pressure and Pulse Before Treatment

| Position | Blood Pressure | Pulse | Comment |
|-----------|----------------|-------|--|
| Recumbent | 100/64 | 84 | |
| Sitting | 59/38 | 88 | |
| Standing | 35/7 | 90-98 | Blood pressure often unobtainable pulse imperceptible (syncope) (cardiac rate) |

Gastric examination showed free acid 0, total acids 4 Histamine was not used

An x-ray film of the stomach and duodenum was negative X-ray films of the colon were negative A film of the gallbladder, taken elsewhere, showed slight impairment of function A film of the abdomen revealed calcification in the region of the adrenal glands X-ray examination of the chest, taken elsewhere, showed calcification of the hilar glands An electrocardiogram was made with the patient both recumbent and sitting There was evidence of coronary artery disease, with a less prominent Q₁ when sitting

In spite of x-ray evidence of calcification in the region of the adrenal glands, it was believed that this was a case of orthostatic hypotension of idiopathic origin The laboratory and clinical picture ruled out Addison's disease as the causative factor

Before therapy was begun, additional clinical studies were made Pilocarpine one-sixth grain (0.01 Gm) was given subcutaneously and there was marked generalized sweating Atropine 1/100 grain (0.0006 Gm) caused no change in blood pressure or pulse rate Carotid sinus stimulation resulted in no alteration of the pulse rate but caused an elevation of blood pressure of about 10 mm of mercury in both the recumbent and the sitting position Response of blood pressure to the cold water test showed no increase In fact, at the end of immersion in cold water the systolic blood pressure fell 10 mm and the diastolic 8 mm of mercury At the end of two minutes the blood pressure returned to its former level Representative readings of the blood pressure and pulse before treatment are given in table 1

Simple flexing of the knees in a sitting position caused the blood pressure to fall 16 mm of mercury A sharp fall of blood pressure occurred after eating Advantage of this observation was taken during treatment in that two main feedings a day were given, with only milk and crackers at noon

Course—Administration of a high salt diet supplemented by additional sodium chloride, both in capsules and intravenously resulted in no improvement

Ephedrine sulfate was given in gradually increasing doses, attaining a maximum of three-fourths grain (0.05 Gm) every two hours for six doses The maximal blood pressure readings obtained in the various positions were as follows recumbent, 148/104, sitting, 84/64, standing 38/22 with dizziness after one minute

This was supplemented by thyroid extract strychnine and an abdominal binder, with no appreciable benefit

Benzedrine sulfate was next tried This was given in doses of 20 mg at 7 a m 10 a m and 2 p m, with no

material benefit This drug was not used in large dosage or for a sufficient period of time to warrant any definite conclusion

Pitressin was then used hypodermically in doses of 1 cc subcutaneously Representative readings forty-five minutes after injection were as follows recumbent, 170/102, sitting, 160/100, standing, 90/70

Using this preparation, the patient walked for the first time without weakness, dizziness or syncope However, she experienced substernal and abdominal distress and pain in the back following its administration The substance was used four times a day for a reasonable length of time and it was found that the peak blood pressure was reached about forty-five minutes after injection Its effect was not noticed after an hour and a half Later it was used in conjunction with ephedrine sulfate Pitressin was also tried by the nasal route, but no benefit was derived Since pitressin was inconvenient for the patient to administer to herself and since it was associated with untoward symptoms such as distress in the chest and abdominal discomfort, it was discontinued

As none of the aforementioned drugs proved entirely satisfactory or practical, neosynephrin hydrochloride was tried Unfortunately during its early use it was discontinued because of an intercurrent attack of pyelitis with chills and fever It might be noted that no alteration of blood pressure occurred during the febrile illness To our knowledge this drug had not been used previously in the treatment of orthostatic hypotension, and the effective dosage could be determined only by trial It was found that the blood pressure rose to a maximum after about one to one and one-fourth hours and remained at the higher level for a variable period of time We were able to elevate the blood pressure from a basal of 80/52 in the morning to a maximum of 186/118 at 5 p m, using 50 mg of the drug every two hours Employing this dosage, the patient was able to be up and about almost at will The blood pressure could be elevated from a basal of 80/50 to a maximum of 192/118, with no untoward side effects There was no associated palpitation, precordial distress, nervousness or undue apprehension, as had been noted following the administration of ephedrine, benzedrine and pitressin Except for a feeling of well being, the patient was unaware of an elevation of the blood pressure The dosage was gradually altered so that on discharge she was taking 30 mg of neosynephrin every hour from 8 to 4 and she was advised to partake of a diet high in salt, with only a small noonday feeding

TABLE 2—Blood Pressure and Pulse After Medication

| Position | Blood Pressure | Pulse |
|-----------|----------------|-------|
| Recumbent | 140/90 | 96 |
| Sitting | 134/84 | 96 |
| Standing | 74/50 | 88 |

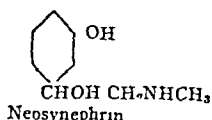

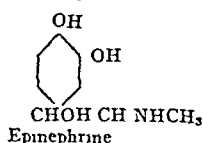

The patient was last seen July 29, 1937, two months after discharge from the hospital She had reduced the dosage to the following 20 mg of neosynephrin at 7 30 a m, 20 mg at 9 o'clock and 20 mg at 12 noon Blood pressure readings and pulse rates recorded on this date, three hours after medication are given in table 2

She had been able to perform all her household duties and partake of three full meals daily Sweating had become more abundant Since discharge, two months previously, she had experienced only one fainting spell For the first time in four years she had been free from weakness and vertigo on standing

COMMENT

Treatment of idiopathic orthostatic hypotension is largely symptomatic It is directed toward elevating the blood pressure so that when the erect position is assumed it will be sufficiently high to allow of normal physical activity Ephedrine and benzedrine sulfate have been the drugs advocated but in this particular instance they did not prove satisfactory The vasopressor effect of pitressin is too short lived and is attended by untoward symptoms which preclude its use In

searching for a suitable sympathomimetic drug, neosynephrin hydrochloride was used. This is a synthetic drug closely related to epinephrine

It may be given by mouth, subcutaneously, intramuscularly or intravenously. It produces a marked elevation of blood pressure as the result of peripheral vasoconstriction and increased cardiac output (increased stroke-volume output). Carl A. Johnson³ reports its use parenterally in the treatment of shock and remarks that, unlike epinephrine and ephedrine, it shows no tendency to produce irregular cardiac rhythm. He remarks further that unpleasant symptoms such as nervousness, apprehension and precordial distress attendant on the administration of epinephrine and ephedrine are not noted with neosynephrin hydrochloride. This has been our experience. Thus far no tolerance for the drug has developed. In fact, the dosage has been decreased from 150 mg to 60 mg daily.

CONCLUSIONS

Neosynephrin hydrochloride was used successfully in the treatment of a case of idiopathic orthostatic hypotension. Its chief advantage is the absence of untoward symptoms, usually associated with the administration of sympathomimetic drugs.

CARCINOMA OF THE CERVIX OF MICE RECEIVING ESTROGENS

W. U. GARDNER, PH.D., EDGAR ALLEN, PH.D., G. M. SMITH, M.D.
AND L. C. STRONG, PH.D., NEW HAVEN, CONN.

During the past three years hyperplastic epithelial lesions of the cervix have been observed following the injection of estrogens into mice. Recently a carcinoma of the cervix has been obtained which has grown following transplantation without continuing the administration of estrogen to the host.

Several investigators have observed abnormal epithelial growths of the uterine cervixes of mice following the injection of estrogens. Loeb, Burns, Suntzeff and Moskop¹ reported a precancerous lesion in one mouse. Following the application of estrogen and 1,2,5,6-dibenzanthracene, Perry² and Perry and Ginzton³ observed lesions in the cervixes of three mice. Localized infiltrating epithelial overgrowths of the cervix were observed in three partially hysterectomized mice and in two mice with intact uteri following estrogen treatment⁴. Recently precancerous or carcinoma-like lesions of the cervix or vagina have been described⁵.

In our laboratory eighteen tumors have been observed in or near the cervixes of mice which have received large amounts of estrogens (500 international units of estrone benzoate or estradiol benzoate⁶ weekly or every two or three weeks) over extended periods. Most of these growths were not apparent in the living animal. Some of the smaller ones were determined only after sectioning and microscopic study (fig. 1). Although even the smaller hyperplastic growths invaded the adjacent mucosa or muscularis, their continued growth independent of further estrogenic stimulation remained undetermined.

Recently a cervical tumor of large size was obtained in a mouse receiving estrogens and was successfully transplanted

into male and female mice of the same inbred strain. It is believed that this experiment affords the first convincing demonstration of a malignant cervical tumor induced by estrogens and indicates that the previously observed epithelial hyperplasias were probably early carcinomas or at least precancerous lesions.

PROTOCOL

A mouse of the C₃H strain received 500 international units of estradiol benzoate every three weeks from an age of 42 to 266 days (a total dose of 5,500 international units). A

Fig. 1—Section of one of the smallest cervical lesions. It was found in a mouse (CBA) which had received weekly injections of 500 international units of estradiol benzoate from the age of 2 to 492 days. It was located at the lower end of the cervical canal. Reduced from a photomicrograph with a magnification of 110 diameters.

mammary tumor appeared at the end of this time and was removed. A second mammary tumor developed twenty-four days later and was removed. At this time weekly injections of 500 international units were started and continued for seventy-five days (5,000 international units). At the age of 359 days a marked enlargement of the pelvis was noted. Five days later the tumor protruded from the vagina and the mouse was killed. A large tumor extending from the bifurcation

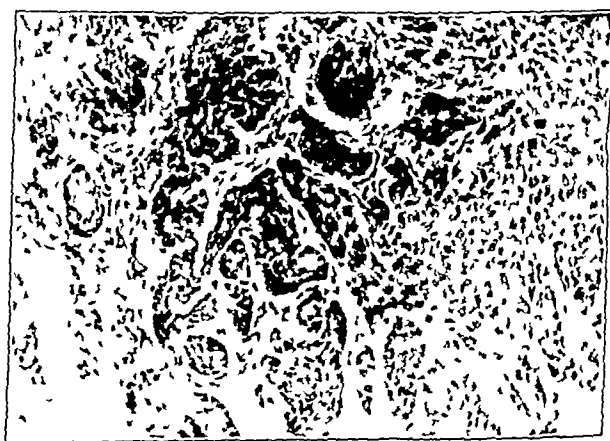

Fig. 2—Section of an area of the largest cervical carcinoma. This tumor was growing very rapidly. It maintained its histologic structure following transplantation and in metastases to the lumbar lymph nodes (protocol of experiment in the text). Reduced from a photomicrograph with a magnification of 200 diameters.

of the uterine horns to the vaginal orifice was found. The entire posterior and lateral walls of the vagina were denuded and inflamed. The cervix was scarcely recognizable. The tumor completely surrounded the rectum and nearly filled the pelvis. The lymph nodes in the lumbar region were enlarged. Small pieces were removed from the lateral margin of the tumor and were grafted subcutaneously into one female and

four male mice of the same strain. All the grafts grew and measured 1 cm or more in diameter in eleven days. At this time one had infiltrated the skin and was removed. The other grafts grew progressively, three invading the skin by the seventeenth day. The tumor is now growing in the second transplant generation.

Although the exact point of origin of this tumor could not be determined on account of its advanced growth, it was

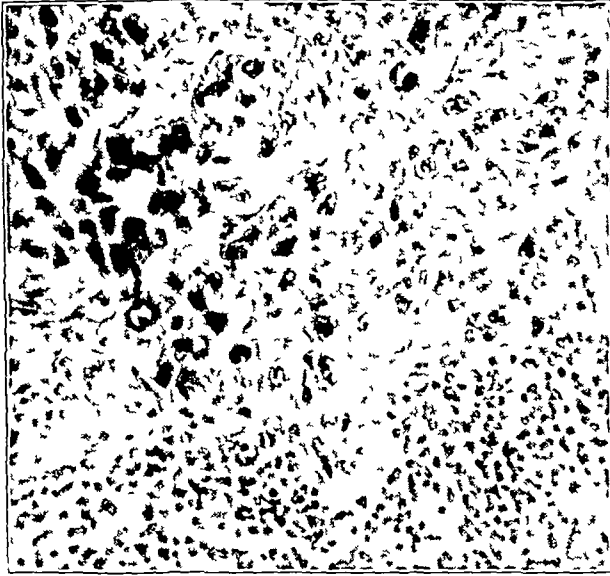

Fig 3—Section of a metastasis of the tumor shown in figure 2 in one of the lumbar lymph nodes. Slightly reduced from a photomicrograph with a magnification of 250 diameters.

histologically similar to the smaller tumors observed in the cervical canals or the vaginal fornices of other mice receiving estrogens. This tumor consisted of squamous cells in dense irregular masses or arranged in columns or cords (fig 2).

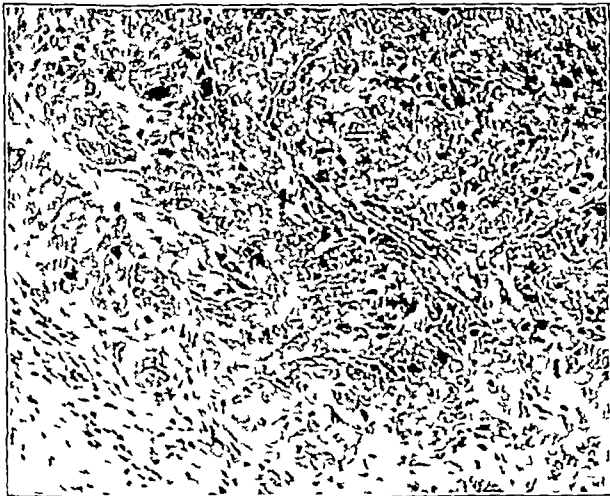

Fig 4—Section of a peripheral area of a transplanted tumor removed eleven days after the initial graft had been placed in the axilla. Slightly reduced from a photomicrograph with a magnification of 200 diameters.

The vaginal surface was infiltrated with leukocytes. In places the tumor cells were continuous with the squamous epithelium of the anterior wall of the vagina. The peripheral parts of the tumor were growing rapidly, extending into the muscles of the rectum and invading the neck of the bladder. The growth of the tumor was primarily in the direction of the vulva, as shown by the involvement of the perineum during the five days it was under observation. Metastatic growths were found in the lower abdominal lymph node (fig 3).

Microscopic study of the excised mammary tumors (one an adenocarcinoma and one an adenocarcinoma of a cystic hemorrhagic type) precludes a metastatic origin of the cervical tumor.

The cervix of the mouse differs greatly in some ways from that of the human being. It contains no glands and is lined by a squamous epithelium. Also unlike the human cervix it shows little tendency to develop spontaneous tumors. We have found no hyperplastic lesions of the cervix in more than 100 old female mice, untreated or receiving injections of sesame oil (solvent for the estrogen). Slye, Holmes and Wells⁷ observed only twenty-two uterine tumors among 39,000 mice (examined post mortem), eleven leiomyomas, seven sarcomas, three adenomas and one teratoma. The first seven tumors observed in our laboratory in mice receiving estrogens appeared in a group of forty-three female mice injected. The earlier development of mammary tumors probably decreases the incidence. Most of the mice with the smaller cervical lesions were killed after the mammary tumors developed. The breast tumors are now being removed in order to lengthen the life of the animals and allow time for development of cervical growths.

SUMMARY

A large carcinoma of the cervix uteri with metastases to the lumbar lymph nodes developed in a mouse following the injection of 10,500 international units of estradiol benzoate over a period of 319 days. This tumor was grafted successfully into male and female mice of the same strain and grew rapidly without further estrogen stimulation. Smaller, invading epithelial growths observed in eighteen other mice are probably pre-cancerous growths or early carcinomas.

ELEVEN DEATHS FROM A CANCER TREATMENT

As we go to press, eleven persons in Orlando, Fla. have died, one other is seriously ill, and two others are mildly ill, following the administration to them by physicians of injections of a treatment for cancer, the preparation apparently grossly contaminated with tetanus toxin. The cancer treatment used was R, series 152, prepared by the Biochemical Research Foundation of the Franklin Institute, Philadelphia, Ellice McDonald, M.D., Director. Dr. McDonald has for some time been interested in the product for cancer called "ensol" and R, we understand, is a product of the type of "ensol" made with a special substrate of cancer tissue. The "ensol" treatment for cancer was first launched in October 1935 by Dr. Hendry C. Connell of Kingston, Ont. At that time, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION published a warning.¹ We quote:

This account of the methods pursued by Dr. Connell in promotion of his product reveals procedures more like those of the charlatan than of the scientific investigator. Moreover, his statement of the method of preparation of his product is so incomplete and confused as to make duplication of his work impossible.

The results he claims are similar to those which have been obtained with a half-dozen other methods. In a few cases there are apparently temporary remissions due to damage of the blood vessels in the tumor. The same effects have been produced by Coley's fluid, by various bacterial toxins, by injection of Witte's peptone and by a number of similar foreign proteins. Results just as good occur with the methods used by most of the cancer quacks. There does not appear to be any real evidence that

⁷ Slye, Maude, Holmes, H. F. and Wells, H. G. *Cancer Research* 5: 96 (April) 1924.
¹ The Connell Cancer Cure editorial. *J. A. M. A.* 105: 1122 (Oct. 5) 1935.

an antitumor enzyme is present in this mixture. Notwithstanding these considerations, newspapers have heralded widely Dr Connell's claims. Great numbers of sufferers from cancer have been stimulated to false hopes. Public officials, university officials, and some Canadian physicians have been led into participation in the promotion of a project which will inevitably bring them grief. The true test of a cancer cure is recovery of the patient and disappearance of the tumor. How many of Dr Connell's patients with cancer will be alive in five years? Time is the true tester of cancer cures—yet newspapers continue to lead cancer sufferers to promoters of cancer cures that have been tested only a few weeks or months. If Dr Connell really realized his responsibility he would have waited to inform the newspapers until he knew whether or not his "discovery" actually had merit. Faith may move mountains but it is yet to be shown that it will cure cancer, even when given in the form of something called "Ensol."

Since 1935 the record of the development of the Connell treatment of cancer has not been inspiring. Researches made on cancer in mice have invariably resulted in failure to demonstrate any value to the method. In August 1936 a bulletin was issued indicating that the Hendry Connell Research Foundation had become affiliated in November 1935 with the Biochemical Research Foundation of the Franklin Institute of Philadelphia. It contains reports of cases treated with "ensol," most of which had been under treatment so short a time that judgment as to the value of the treatment is impossible. In one statement it is said that "382 cases were treated, with a death rate of 47 per cent." The statement is also made that "53 per cent of hopeless and abandoned cases are now alive." Although the period of treatment in most of them was not even one year, it is argued that "ensol does influence the course by partial or complete arrest in cases of advanced cancer."

In October 1936 Dr Charles Phillips² published in the *Texas State Journal of Medicine* a report of a visit he had made to Kingston. Here he describes the manufacture of "ensol" as follows:

Bacillus histolyticus is a relatively harmless germ, elaborating during its growth an active enzyme which, if it were allowed to act upon protein material at body temperature, would more or less completely dissolve it by enzyme action. By trial, it was found that this germ would autolyze cancer as any other protein, and then the crux of the whole plan was reached when it was believed that the resulting enzyme solution, if given in suitable dose to a suitable cancer patient, would cause regression of that cancer selectively. In this way, the general rules about tissue specificity and immunology were followed. When the program was finally worked out, it called for careful laboratory handling of the germs inoculated onto pieces of cancer removed from a fresh cancer and finally for giving the autogenous solution, now called Ensol, to the patient from whom the piece of cancer was excised. I saw racks of tubes, in the incubator, which had been inoculated for seventy-two hours with *Bacillus histolyticus*. The fluid was filtered through Berkefeld filters and held for about twelve hours for clarity as sterility control, the liquid tubed and labeled with Ensol batch number and date, and this was then ready for injection into the patient. Both the autogenous Ensol and stock Ensol made from any fresh available carcinoma material were tried, but before long it was found too difficult to stick closely to the autogenous method. Thus, gradually, a certain amount of specificity was lost. The reputation of the new treatment brought numbers of cancer cases to Kingston, and so there was no actual dearth of fresh material. Aseptic technic was used throughout the removal of the tissue and its laboratory development into Ensol, but I found a poorly equipped place for work and a number of potential breaks in straight bacteriologic technic under the supervision of a relatively inexperienced assistant technician.

He appeared to me to be doing the best he could under difficulties of being temporarily housed in the basement of the physics building of Queen's University.

In October 1936 letters became available in the headquarters office of the American Medical Association indicating that Dr Ellice McDonald was doing his utmost to promote the "ensol" method, endeavoring to establish in Chicago an office to which patients could be referred and offering, indeed, to pay the expenses of a physician to spend two months in Kingston and then to become established in Chicago. He said "It looks as if we could refer you enough patients to make it well worth your while." In another letter he said:

I am sure in the past four months I could have sent twenty such patients who will require at least one hundred injections each, if you had knowledge of the treatment and had had direct experience in its use. You could carry on this treatment as well as your own practice. If it got to be too much for you to handle, you could easily impress an assistant, and I am inclined to think in the near future, when this treatment really gets going, it could be made quite a real practice and also a reasonably remunerative one. We would like to have some doctor in Chicago who had knowledge of the treatment and who is able to give first hand advice in consultation with the other Chicago doctors who are using it. We could control much for you by making you more or less a central dispensary for the distribution of ensol. We cannot make you the sole distributor, but we could wangle it around so that most men would have to come to you in consultation.

Apparently since 1936 the Hendry Connell Research Foundation of Kingston and the Biochemical Research Foundation of the Franklin Institute have been able to secure physicians in various portions of the United States to act as distributing agents and experimenters with "ensol."

On Friday, March 25, Dr T. A. Neal of Orlando, Fla., who has for some time been using "ensol" in his practice, treated his patients with the product called R, series 152. Some of the patients reported reaction in the form of a sore arm on March 26. On March 27, many became ill. By March 28 all were seriously ill with symptoms identical with those of tetanus. By March 31 seven had died, four were seriously ill and two were expected to die. Postmortem examination revealed cerebral edema and changes in the viscera. Up to March 31, tests had been made with the product called "ensol." At that time Dr Neal, who had naturally been extremely disturbed about the matter, pointed out that he had used also the product called R, series 152. A vial of this preparation was injected into three guinea pigs, and three others were injected with "ensol." The three guinea pigs injected with R, series 152, died and the three with "ensol" did not die.

Immediately on receiving the news of this event by long distance telephone from Orlando, Fla., the headquarters of the American Medical Association notified the Food and Drug Administration and the National Health Institute in Washington, D. C. Both organizations immediately sent investigators to Orlando, Fla., to Kingston, Ont., and to Philadelphia. Dr H. A. Day of Orlando, president of the Orange County Medical Society, who has been active in the investigation, now writes that on April 1 one patient who had been taking this treatment came in bringing with her a vial of R, series 152. This patient had developed symptoms of tetanus. According to her statement, she had received two doses of R, series 152, one on March 29 and one on March 30. All specimens of R, series 152, were obtained and studied. Part of the material was shipped to Washington. The evidence as we go

² Phillips, Charles. Connell Cancer Treatment. Its Present Status. *Texas State J. Med.* 32: 406 (Oct.) 1936.

to press, indicates that all the animals receiving only R, series 152, dated March 7, died of tetanus. The other animals injected at the same time with R, series 152, and with large doses of tetanus antitoxin did not die. It is now announced also that Ellice McDonald, director of the Biochemical Research Foundation, claims that the bacterial filtrate has no contamination. Nevertheless, all of the material under investigation has been recalled and the names of physicians of the United States who are using the product have been turned over to government agencies. Moreover, C. G. Power, health minister of Ontario, has forbidden all distribution of "ensol" until the investigations now under way are completed. The conclusion is inevitable that the product called R, series 152, which is alleged by the Biochemical Research Foundation of the Franklin Institute of Philadelphia to be a type of "ensol," is the product which contained sufficient tetanus toxin to kill those in whom it was injected. Appreciation is due to physicians of Orange County, Fla., for their prompt action in exposing this matter and for their activity in determining all the facts as soon as possible. The investigations by the United States Public Health Service and the Food and Drug Administration are proceeding in an endeavor to fix the responsibility for this tragedy.

ROCKY MOUNTAIN SPOTTED FEVER

R. R. PARKER, PH.D.

Director, Rocky Mountain Laboratory, United States Public Health Service
HAMILTON, MONT.

The rickettsioses of man include a number of tick, louse, flea and mite borne diseases caused by infectious agents termed rickettsiae, the known characteristics of which suggest that they may be a group of microorganisms intermediate between bacteria and filtrable viruses. The literature and the classification of these rickettsial diseases have been and still are in a somewhat chaotic condition, owing, on the one hand, to the fact that an unavoidable lack of knowledge of the identity of the diseases observed has frequently necessitated that they be referred to by local or other equally unfortunate designations and, on the other, to premature attempts to classify them on the basis of geographic occurrence or with regard to the nature of their respective insect or arachnid vectors. Some semblance of order is now becoming apparent, however, as the result of more recent and more logical efforts to segregate them by the more significant criteria afforded by combined epidemiologic, pathologic and serologic data. On this basis three groups seem quite definitely established—the typhus group, the Rocky Mountain spotted fever group and the Japanese river fever group. Several are still unassociated. The typhus group consists of historic louse-borne typhus and endemic flea-borne typhus, but the question of whether they are caused by the same virus as altered by passage through different vectors is still unsettled. The Rocky Mountain spotted fever group includes the following tick-transmitted diseases: Rocky Mountain spotted fever of North America, São Paulo exanthematic typhus of Brazil and boutonneuse fever of southern Europe and northern Africa. Here again one finds uncertainty as to how nearly identical they should be considered. The

Japanese river fever group consists of several more or less closely related mite-borne infections of southern Asia, Japan, Formosa and Oceania.

The two rickettsioses in which North Americans are interested are endemic typhus and Rocky Mountain spotted fever. The latter is the more widely distributed and the more important economically and is the subject of this paper. The data offered will be presented under four sectional headings: (1) ticks concerned in the maintenance and transmission of the virus, (2) the virus and the disease in nature, (3) the disease in man and (4) prophylaxis.

TICKS CONCERNED IN THE MAINTENANCE AND THE TRANSMISSION OF THE VIRUS

Three ticks are proved transmitting agents of the virus of Rocky Mountain spotted fever: the Rocky Mountain wood tick, *Dermacentor andersoni*, the American dog tick, *D. variabilis*, and the rabbit tick, *Haemaphysalis leporis-palustris*. All three of these ticks occur in both the United States and Canada, while *variabilis* extends southward into Mexico and the rabbit tick into Central and South America.

The Rocky Mountain wood tick is found throughout the Rocky Mountain region and adjacent areas, extending into the eastern portions of the Pacific Coast states and into western North and South Dakota and Nebraska. It is abundant in southeastern British Columbia and occurs in parts of southern Alberta and at least southwestern Saskatchewan. The larval and nymphal stages engorge on a great variety of rodents and certain of the smaller carnivores, most of which are susceptible to spotted fever. The adults infest mainly large animals, wild and domestic, but occur to some extent on small animals, particularly jack-rabbits and porcupines. The larvae are active during the summer, the nymphs and adults during the spring and early summer. In the higher altitudes all stages may occur somewhat later in the season. The life cycle of the Rocky Mountain wood tick is normally completed in two years. The adults bite man freely, and the nymphs occasionally attach to children.

The American dog tick is widely distributed throughout the Central and Eastern states and is fairly numerous in many sections. East of the Rocky Mountain region it overlaps the eastern limit of the Rocky Mountain wood tick. On the Pacific Coast it is found in western California and occasionally in southwestern Oregon. In Canada it occurs eastward from southern Manitoba and has been reported in Labrador. Information concerning the biology of this species is relatively sketchy compared to our knowledge of the Rocky Mountain wood tick. The early stages, like those of the latter tick, feed on rodents, but apparently on a much smaller range of species. Some species of mice are recognized to be important hosts. The common name of this tick results from the prevalence of the adult stage on dogs. However, this stage is common on deer and is also found on the larger domestic animals, especially cattle, and even, to some extent, on the smaller wild animals. Data concerning the seasonal occurrence of the immature stages are incomplete. The nymphs apparently engorge over a period of some months and have been found feeding even during the winter. The adults appear later in the spring and remain active later into the summer than do those of the Rocky Mountain wood tick. This tick also bites man freely.

From the Rocky Mountain Laboratory of the National Institute of Health.
Read before the first Rocky Mountain Medical Conference, Denver, July 21, 1937.

The rabbit tick has the widest distribution of any of the three species mentioned. It occurs essentially throughout the United States, extending southward into South America and northward into central Alaska and into Canada at least as far as the southern end of Hudson Bay. All three stages are limited to various species of rabbits (some of which are more heavily infested than others) and to certain ground-frequenting birds, especially certain game birds. In the northern part of the United States it is prevalent from early spring until early fall. In the South its seasonal occurrence is considerably extended. When conditions are favorable, its life cycle is completed in one year. It occurs on man only rarely. In contradistinction to the two ticks just discussed, it carries consistently a very mild strain of spotted fever virus.

There are five other species of ticks in the United States that are potential transmitting agents. Under laboratory conditions they have been demonstrated to be fully as efficient vectors as the proved carriers. It seems probable that two of these ticks, *D. occidentalis*, the Pacific Coast tick, of California and Oregon, and *Amblyomma americanum*, of the South Central and the Southeastern states, are actual natural carriers. This has not been proved, but there is suggestive evidence. The latter species has been reported from as far north as southern Manitoba. The other three species are *Amblyomma cajennense*, which occurs in the southern tips of Texas and Florida and is the known transmitting agent of São Paulo exanthematic typhus, a disease prevalent in the vicinity of São Paulo, Brazil, which is immunologically identical with Rocky Mountain spotted fever, *Rhipicephalus sanguineus* the brown dog tick, which is abundant along the Gulf Coast and occurs northward sporadically as far as Minneapolis and westward to Phoenix, and is a known carrier of boutanense fever in southern Europe and northern Africa, and, finally, *D. parumapertus*, which occurs on rabbits in the southern Rocky Mountain region and along the Pacific Coast northward into Oregon. The host relationships of all these five species are such that any tick not already carrying infection is likely to do so sooner or later.

Three of these species frequently bite human beings, and, of the other two, the brown dog tick does so commonly in Europe and Africa but is little known as a parasite of man in North America, while *D. parumapertus* bites man but rarely and can be concerned only as a possible infection-carrier in nature.

THE VIRUS AND THE DISEASE IN NATURE

Most studies concerning the virus and spotted fever in nature have been made in relation to the Rocky Mountain wood tick, and the statements which follow refer to this tick unless otherwise stated.

The actual mechanism by which the virus is maintained and perpetuated in nature has not been definitely demonstrated. The three following sets of factors are evidently concerned, but their relative importance is not clear.

1 *Stage to Stage and Generation to Generation Transmission of the Virus in Ticks*—In the case of the three proved tick carriers, infection acquired by larvae or nymphs is passed on to the adult stage and from a certain percentage of infected females it is passed on through the eggs to the larvae of the next generation. Also infected male ticks may infect females during impregnation. It may be that this

mechanism is all that is necessary to assure continuity of the virus in nature, although theoretically it can be shown that this is unlikely.

2 *Stage to Stage Transmission of the Virus in Ticks Plus the Starting of New Lines of Tick Infection Each Year by the Simultaneous Feeding of Infected and Noninfected Ticks on a Susceptible Host*—When infected larval, nymphal or adult ticks feed on susceptible hosts, the last named presumably become infected, and noninfected ticks which engorge on these hosts during the infectious period may acquire the virus. The following season the next succeeding stage of the tick may in turn infect its host and through it still other ticks. New lines of tick infection can thus be started each year. It was formerly supposed that only larvae and nymphs would normally function in this manner, but now that adult-tick hosts such as dogs and sheep are known to be mildly susceptible, it is apparent that the male and the female ticks may also have a part. This seems particularly likely in the case of the American dog tick.

3 *The Occurrence of Spotted Fever Virus in the Rabbit Tick*—As previously mentioned, the rabbit tick, in contradistinction to the Rocky Mountain wood tick and the American dog tick, consistently carries an extremely mild type of the virus. When virus-carrying rabbit ticks are tested by means of laboratory animals, the resulting infection is usually inapparent, that is, it is so low grade that the animal becomes immunized without any febrile reaction. Sometimes there are mild symptoms. The relationship of this tick to the spotted fever problem, particularly to the maintenance and perpetuation of the virus in nature, offers an intriguing field for study. It has the widest geographic distribution of the three proved carriers, and spotted fever virus has been demonstrated in it far north of any known occurrence of Rocky Mountain spotted fever in man and far beyond the northern distributional limits of the other two carriers. It is evident therefore that the virus can persist in the rabbit tick independently of the Rocky Mountain wood tick or the American dog tick. But is infection in the last-named ticks independent of infection in the rabbit tick? The answer to this question is less apparent. The Rocky Mountain wood tick and the rabbit tick meet on rabbits. A rabbit therefore is a medium through which infection can apparently be passed back and forth between these two species of ticks. The extent to which *D. variabilis* infests rabbits is unknown. Some species of rabbits average from a few hundred to several thousand rabbit ticks per individual, depending on the part of North America concerned.

The percentage of ticks that carry infectious virus has been studied mainly in the Rocky Mountain wood tick and is different in different localities and from year to year even in the same locality. It is frequently less than 1 per cent and rarely exceeds 5 per cent, although in small, localized areas as high as 11 per cent has been demonstrated. Local tick populations which have shown 3 per cent to be infectious one year have the next year failed to show evidence of a single infected tick. In the case of the rabbit tick as studied in Minnesota, Dr R. G. Green of the University of Minnesota Medical School and I have been able to show infection in between 3 and 4 per cent.

The maximum level of virulence of spotted fever virus varies in different foci in which the disease is endemic, but in most areas it remains reasonably con-

stant from year to year. In some of these foci the maximum level is high and causes a correspondingly high mortality in laboratory animals or in man, in others it is low and inapparent infections are produced consistently. In most areas it is intermediate.

The virus in any individual Rocky Mountain wood tick of a local tick population may range in virulence from a nonimmunizing, nondemonstrable phase to one of the prevailing maximum local virulence. This is doubtless true also of the virus in certain of the other proved and potential tick carriers. The phase present at any particular time depends on the season of the year and how recently the tick may have ingested blood. In a fasting, hibernating Rocky Mountain wood tick or one just emerging from hibernation, the virus is usually either completely inactive or in a phase which causes inapparent infections when injected into laboratory animals. However, if such a tick is incubated or is allowed to ingest blood, the virus becomes "reactivated" and soon reaches its maximum potential virulence.

At this point it is worth while to consider the question of whether or not the occurrence of Rocky Mountain spotted fever in the Central and Eastern states has been the result of a natural spread or of transportation of the virus from the Rocky Mountain region. While it is now recognized that an intensive spread of both the tick and the virus has been in progress within the range of the Rocky Mountain wood tick ever since settlement of the West was begun, yet there is no evidence of any consequential outward expansion of the range of this tick or of the area within which it is the agent of the transmission of spotted fever. Nor are there any data which suggest that transportation of the tick by stock or other animals shipped from the Rocky Mountain region has ever resulted in establishing in nature either this tick or the virus of spotted fever at any point in any of the twenty-four Central and Eastern states in which Rocky Mountain spotted fever has been reported since 1930. If the virus of this disease as met with in *D. variabilis* was derived from the ticks of the Rocky Mountain region, it would seem probable that a clearly marked trail would have been left along the railroad lines over which stock has been shipped eastward for many years. This is not the case, however. It is also odd that, under such circumstances, Rocky Mountain spotted fever should be most prevalent in the eastern portion of the *D. variabilis* range rather than the western. Other considerations relating to the biology of both *andersoni* and *variabilis* are concerned also but are too lengthy to discuss.

On the other hand, it is now recognized as probable that spotted fever infections have been occurring in some of the far Eastern states for at least thirty years, and it seems not at all impossible or improbable that the virus of this disease has been endemic in the Eastern and the Central states fully as long as in those farther west.

In connection with spread, it is worth noting that fully as high a percentage of spotted fever-infected rabbit ticks is met with among those taken from birds as among those collected from rabbits, and since birds of the species involved move about considerably within at least limited areas, it may be readily comprehended that this tick and its bird hosts form an excellent means for intensive local distribution of the virus and possibly in some instances for its transportation over longer distances.

THE DISEASE IN MAN

In the United States, Rocky Mountain spotted fever is endemic in at least thirty-nine of the forty-eight states. It has been known to be present for many years in all eleven of the Rocky Mountain and Pacific Coast states and more recently in North and South Dakota, and since 1931 it has been reported from twenty-six of the Central and Eastern states. It is most prevalent in the northern Rocky Mountain region and adjacent areas and in parts of North Carolina, Virginia and Maryland. It is likely endemic also in at least some of the Central and Eastern states from which it has not yet been reported.

The greatest number of cases occur in groups of the population engaged in some outdoor occupation or pursuit, principally agriculture. Persons living in range areas, particularly those handling sheep, are in the greatest danger. Other groups affected include hunters and trappers, prospectors and miners, forest service personnel, survey crews, highway construction workers, section hands on railroads, and those who only occasionally visit infected areas for business reasons or as fishermen, picnickers, campers and tourists. In the West only a small percentage of cases occur in city dwellers. This percentage is somewhat higher in some parts of the East. A few cases have been known even in persons who had been confined to bed for weeks. In such instances infected ticks have been brought into the city or home by some intermediary person or animal.

Age and sex incidence depend both on occupation and on whether families live actually within, or only adjacent to, tick-infested areas. In the sagebrush desert regions of the western part of the United States most infections are contracted by men, because of occupational hazards. When families live within infected areas, however, a much higher percentage of cases occurs in women and children. The considerable percentage of cases in women and children in the eastern part of the United States is probably due in part to the fact that the eastern transmitting agent, the American dog tick, infests the dog, a household animal. The Rocky Mountain wood tick is found on dogs far less frequently.

In the West, most of the cases occur during the spring and early summer and the greatest number in April and May, the season of prevalence of the Rocky Mountain wood tick. In sections of higher altitudes (Wyoming, for example), however, the danger season extends further into the summer. Occasional cases have been reported during the late summer, fall and winter months. Persons with fall and winter infections have usually become infected in mountainous areas. In the East, most cases occur in the summer, the season of greatest activity of the American dog tick.

Annual incidence varies and is influenced markedly by meteorologic factors that affect the duration and the intensity of tick activity. Sometimes there is a complete absence for a series of years of cases within a locality in which the disease is endemic. In the Rocky Mountain region the trend of prevalence over considerable periods has been and continues to be more or less definitely associated with conditions incident to settlement and the subsequent type of local agricultural development. In some sections the activities incident to settlement, such as the clearing and bringing under cultivation of large areas of timber or of sagebrush, have created, temporarily or even for considerable periods, the very conditions essential for an

RIBOFLAVIN

PHYSIOLOGY AND PATHOLOGY

A G HOGAN, PH D

COLUMBIA, MO

increasing prevalence of both ticks and spotted fever. The ultimate trend of local prevalence, however, is dependent on the type and extent of permanent agricultural development. In areas where agriculture has become intensive, prevalence has decreased, while in those where it has remained extensive, particularly in range country, it has usually continued about the same and in some instances has increased. The best example of decreasing prevalence is in the Snake River Valley of southern Idaho where there were formerly several hundred cases a year and are now less than fifty. The outstanding example of increasing prevalence is eastern Montana, where spotted fever was rare before 1914 but has since been gradually increasing. There were over 100 cases in 1935. This increasing prevalence has been due at least partly to the progressively more intensive distribution of the tick vector, a natural result of the activities of development. Ticks are now numerous in parts of eastern Montana where they were unknown twenty years ago.

The virulence of the infection in man varies with locality and in any selected area is correlated with the maximum level of virulence of the virus strains in the local tick population. Thus, in most foci the case fatality rate remains reasonably constant. In the Bitterroot Valley section of western Montana the death rate for adults averages about 80 per cent and for children is 37.5 per cent. A high case fatality rate, however, is not confined to the Bitterroot Valley, as is so commonly believed, but prevails in other parts of western Montana, in certain localities in Wyoming and Oregon, in all affected portions of northern Idaho and along the extreme eastern edge of Washington. In other foci the case fatality rate varies to a minimum of at least 10 per cent. In a few areas it appears to be gradually increasing. Southern Idaho again affords a good example. In former years, when cases were more numerous, the death rate was estimated to be about 5 per cent. At the present time with fewer cases, the rate is from 25 to 35 per cent.

To the best of present information spotted fever infections are acquired only through the medium of ticks, usually by tick bite. There is no characteristic lesion at the site of tick attachment, and not infrequently the site of the bite cannot be found. If a lesion not due to irritation is present it is likely the result of secondary infection or some tick-borne agent other than the spotted fever rickettsia. Occasionally there is an enlargement of the regional lymph nodes draining the area. Some few infections are probably contracted through the skin by contamination of the body surface with tissues of infected ticks. This contamination may occur as a result of hand picking ticks from domestic animals.

In a previous section I have referred to the phenomenon of "reactivation." This bears an important relationship to the transmission of infection to man. The virus contained in a tick which attaches in the early spring does not usually become frankly infectious for eight hours or longer after attachment, i.e., until the virus has been "reactivated." Later in the season, however, "reactivation" has been at least partially accomplished by the prevailing warmer temperatures, and infection apparently may occur more quickly. Were virus "reactivation" not necessary, there would be many more infections. I have known infected ticks to feed for as long as three days without transmitting the virus.

(To be continued)

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. The articles will be published later in book form.—Ed

In the course of their studies on pellagra Goldberger and Lillie¹ used rats as experimental animals and produced a characteristic deficiency disease. Ophthalmia and bilaterally symmetrical denuded areas were the most important symptoms, and these are still the most common and most characteristic. Goldberger and Lillie reported that "some of the animals have developed a dermatitis at one or more of the following sites: ears, front of neck and upper part of chest, forearms, backs of forepaws, shins and the backs of the hind paws." Other workers² also observed the more severe symptoms but they are comparatively infrequent. Goldberger's description was reviewed by Sure,³ so additional details will be omitted. The agent that prevents the lesions was designated by Goldberger as the P-P (pellagra-preventive) factor. American biochemists designated the new vitamin as G, the British workers called it vitamin B₂. Goldberger made a very important contribution, but, as is now known, most of the symptoms of the rat disease he described are prevented by riboflavin. This substance does not prevent pellagra, so the two diseases are not analogous.

Goldberger and Lillie did not report the incidence of the symptoms due to a lack of their P-P factor, but other workers have encountered the most extreme variability. Some workers report no symptoms except failure to grow. Others produce them readily in one trial and have difficulty in another.⁴ Roscoe⁴ reported that of 191 rats deprived of vitamin B a little less than 57 per cent developed dermatitis in an average period of ten weeks. For some years these inconsistencies were puzzling, and it was not possible to eliminate them until the technique was further improved. Hogan and Hunter⁵ had announced that the new factor, vitamin G, is destroyed by ultraviolet irradiation. It eventually developed that this irradiation not only destroyed vitamin G (or riboflavin in the more recent terminology) but also destroyed another vitamin which had not been recognized at that time. Since the symptoms of these two deficiencies sometimes have a superficial resemblance, neither could be sharply defined until both were more or less fully understood.

5 Hogan, A. G. and Hunter, J. F. The Plural Nature of Vitamin B. *J. Biol. Chem.* 78: 433 (July) 1928.

The technic of Hogan and Hunter was modified⁶ in certain respects, and when the modified procedure was used a characteristic dermatitis developed in every experimental animal that survived the depletion period. These lesions have only a superficial resemblance to those described by the previously mentioned workers, and since they did not appear when the rations contained corn starch it was suggested that there are several types of dermatitis, each due to a different deficiency. This suggestion was soon corroborated. The experimental procedure not only demonstrated that there are two different types of lesions, each the result of a different deficiency disease, but it made it possible to produce either, consistently, and with an incidence of practically 100 per cent. It has been suggested⁸ that in conformity with the American system of nomenclature the new vitamin be designated as H. It is B₆ in the British terminology. Since the term vitamin G as first used included at least two vitamins, there is no agreement as to what its precise meaning should be now. Evidence obtained with the rat shows that the old vitamin B complex contains vitamin B (B₁), riboflavin and H (B₆), there is no doubt that at least one more must be added² and several more have been suggested.

The ration of Richardson and Hogan proved to be well adapted also for studies on riboflavin deficiencies. Unpublished data show that 155 rats were on rations deficient in this substance long enough for the characteristic denuding symptoms to develop. Of these, 136, or 95 per cent, became denuded in periods ranging from six to twenty-four weeks. Some of the remaining 5 per cent were used for other purposes during that period, so with the technic now available practically every rat that survives long enough will develop the typical symptoms.

IDENTITY OF VITAMIN G (B₂) AND RIBOFLAVIN

To digress for a moment, Blyth⁹ had demonstrated the presence in milk of a pigment which he called lactochrome. In more recent years several groups of workers became interested in this substance, and more or less concentrated preparations were obtained¹⁰ from milk, liver, heart, kidney, muscles, egg white and yeast. Since the pigment was first isolated in crystalline form¹¹ from milk, it was designated as lactoflavin, but it is more commonly known as riboflavin in the United States. This substance is yellow, with a characteristic green fluorescence.

Kuhn and his collaborators were interested in vitamin G (B₂), and early in their work they observed a parallelism between vitamin B₂ activity and the intensity of the yellow color and green fluorescence. Both

the vitamin and the pigment were destroyed on exposure to light, so it was assumed that they were identical, and this assumption was confirmed.¹² Of the various animal tissues examined liver and kidney contain the largest amount. One unit is contained in from 0.2 to 0.4 Gm of fresh weight of liver and kidney and in 0.5 Gm of ox heart. The heart muscle contains about five times as much of the vitamin as does striated muscle. Their unit is from 8 to 10 micrograms of riboflavin, the amount that permits a gain by a rat of 40 Gm in thirty days. Edgar and her collaborators¹³ report that approximately 40 micrograms daily is required for optimum growth.

Gyorgy and his collaborators observed that if liver or yeast is extracted in the cold a small portion of vitamin B₂ will dialyze, but that if the extracting fluid is heated then it all dialyzes readily. Evidently some of the vitamin is free and the remainder is bound to a carrier of high molecular weight. This is also true of riboflavin, some is free and some is bound to a colloidal carrier, so the pigment is probably both an enzyme and a vitamin. When the union is broken the enzymic properties are lost, but the vitamin effect remains.

Karrer, Salomon and Schopp¹⁴ determined the free flavin in liver, also the amount that is combined. One determination showed 76 per cent, another 53.5 per cent, in high molecular weight combination. In cow's milk about 90 per cent of the total amount is free, but Ellinger and Koschara¹⁵ reported that in human milk the pigment is attached to a colloidal carrier, probably albumin.

More recently Karrer¹⁶ and Kuhn¹⁷ almost simultaneously accomplished the synthesis of riboflavin, and Gyorgy¹⁸ showed that the biologic activity of the synthetic product is identical with that of the naturally occurring form. Its activity is the same, whether administered orally or intraperitoneally.¹⁹

RIBOFLAVIN AND CELL RESPIRATION

Various physiologic roles have been ascribed to riboflavin, but the only one concerning which there is no dispute is that it has some function in the oxidation processes of the cell. Our knowledge of these reactions is chiefly due to Warburg and Christian. It is impossible in this paper to give an adequate review of their researches, but they²⁰ isolated a yellow oxidation enzyme from bottom yeast, which was of a new type, as shown by the fact that it is not inhibited by carbon monoxide or by hydrocyanic acid. The active group of the enzyme, the pigment portion, is bound to protein and is easily detached.²¹ This protein-free pigment is yellow, with a green fluorescence, and according to Warburg and Christian it has no enzymic activity.

In studies of the properties of the yellow enzyme, Robison's hexose-monophosphate ester was used as the substrate. It developed though that in the oxidation of the ester two other catalytic agents are required. These are a second enzyme (dehydrogenase or intermediary enzyme) which is colorless, and a coenzyme. The reactions of this type of respiration have been summarized²² as follows:

The entire system, then, that oxidizes hexose-phosphoric acid to phosphohexonic acid consists of a dehydrogenase (or intermediary enzyme), a coenzyme, the yellow oxidation enzyme and molecular oxygen.

Important details additional to our knowledge of the yellow oxidation enzyme were added by Theorell.²³ The enzyme was purified and found to have a nitrogen content of 15.5 per cent. A salt-free solution was then dialyzed against dilute hydrochloric acid and thus broken into two component parts, a protein and a fluorescent pigment, neither of which was able to transfer oxygen. They could be recombined, however, and the combination exerted normal enzymic activity. This protein fraction is specific and cannot be replaced by other native proteins such as globin. Theorell succeeded in isolating the prosthetic group of Warburg's yellow enzyme, which was identified as flavin phosphate. That the prosthetic group of yellow enzyme is a phosphoric acid ester is of considerable physiologic significance. It is true that free riboflavin may combine with the colloidal carrier to form an enzyme,²⁴ but this is probably of little quantitative significance.

A somewhat different approach to the physiology of riboflavin is due to the observations of Banga and Szent-Gyorgyi.²⁵ They used the heart muscle of swine and prepared a concentrate of "respiration-coferment." This concentrate also contained a golden yellow pigment, which they named "cytoflav." The absorption spectrum²⁶ of cytoflav showed that it has some structural similarity to Warburg's yellow enzyme, and it was shown by Kuhn and Rudy²⁷ that cytoflav is the phosphoric acid ester of riboflavin. It is significant that a glycerol extract of the small intestine of rats in 0.01 molar phosphate solution will convert flavin quantitatively to the phosphoric acid ester.²⁸

Presumably the necessity for including riboflavin in the diet is that it is an essential constituent of the yellow oxidation enzyme that cannot be synthesized by the animal cell. It is probable, then, that the vitamin activity of flavin is due to the fact that it forms an ester with phosphoric acid, and this ester combines with protein to form the yellow oxidation enzyme. Apparently, if no hemin substances are present, all of the cell respiration is accomplished by Warburg's yellow ferment. On the other hand, if iron compounds are present it may be that only a small part of cell respiration is due to this enzyme.

RIBOFLAVIN IN TUMOR TISSUE

As would be expected, the respiration of tumor cells has been given intensive study and a low concentration of vitamin B₂ (riboflavin) in carcinoma tissues has been reported.²⁹ Von Euler and Adler³⁰ found from 0.5 to 1 microgram of riboflavin per gram of fresh weight in the Roux sarcoma (chick) and from 0.025 to 0.5 microgram in the Jensen sarcoma (rat). Elliott, Benoy and Baker³¹ studied two types of tumor tissue, the Philadelphia No. 1 rat sarcoma and the Walker No. 256 carcinoma. Of the various oxidative mechanisms studied, Elliott and his associates concluded that two and possibly three are not active in tumor tissue. They suggest that the low concentration of flavin may explain the failure of tumors to oxidize lactate or malate, though lack of enzymes or coenzymes would explain the failures equally well.

STORAGE AND EXCRETION OF RIBOFLAVIN

It has been reported³² that the flavin content of organs cannot be much increased, even a tenfold increase in the amount of riboflavin consumed increased very slightly the amount of the yellow enzyme in the liver. On the other hand, the body guards its store of this substance and even in rats that die for lack of riboflavin the amount in the liver, kidney and heart is still about one third of the normal level. When flavin was added to the diet of depleted animals, growth started before the reserves in the organs were restored to the original amount.

When the diet is adequate riboflavin is a normal excretory product, and Koscharka³³ isolated crystalline uroflavin from urine. The typical yellow color of urine, however, is due to a different compound. According to Vivanco³⁴ the total excretion of flavin in the urine and feces of a rat is from 3 to 5 micrograms daily, and the feces contain about twice the amount present in urine. Within fourteen days after total deprivation of vitamin B₂ no flavin was excreted in the urine and growth was suspended.

The most extensive study of riboflavin excretion by man was conducted by Emmerie,³⁵ who reported that the daily elimination in the urine of males is from 819 to 1,250 micrograms or from 30 to 50 micrograms per hour. However, if the consumption of riboflavin is greatly increased there is a corresponding increase in the amount eliminated. In a continuation of this investigation, Emmerie³⁶ states that the body seems to act as a reservoir for flavin. On a very low intake the excretion exceeds the intake and on a high intake the excretion lags behind. After thirteen days of flavin restriction the urinary excretion varied between 43 and 60 per cent of the normal amount. Roscoe³⁶ observed a similar train of events. With an increased intake

there was both an increased retention and excretion. The rate of destruction of riboflavin by the body has not been reported, but the observations cited indicate that some destruction does occur. One might estimate from Emmerie's data that a man should receive from 2 to 3 mg of riboflavin daily.

OVERDOSAGE OF RIBOFLAVIN NOT TOXIC

Kuhn and Boulanger³⁷ reported that mice were not injured by doses of 340 mg of riboflavin per kilogram of body weight, roughly 1,000 times the daily requirement. If calculated on the same weight ratio, a man weighing 70 Kg would not be injured by ingesting 20 Gm of lactoflavin, the amount present in 20,000 liters of cow's milk.

RIBOFLAVIN INTAKE AND AMOUNT SECRETED IN MILK

The amount of vitamin G, either in cow's milk³⁸ or in human milk,³⁹ depends somewhat on the amount consumed, but precise data on this point are not available. It has been estimated⁴⁰ that a cow may consume 50 mg of riboflavin in one day and secrete 10 liters of milk containing 1 mg of riboflavin per liter, thus giving a recovery of 20 per cent. Each of these quantities is subject to revision, but they are probably of the correct order of magnitude.

Yellow fluorescence does not appear in the milk of wetnurses on a vegetarian diet⁴¹ but is quite evident if the intake of riboflavin is increased. Muller⁴² observed that after a diet of 250 Gm of ox liver, which contained approximately 4 mg of riboflavin, the yellow fluorescence approached that of cow's milk, provided the total milk production was low. If large amounts of milk were secreted, the flavin was correspondingly diluted. Muller also gave intramuscular injections of riboflavin and stated that 0.75 mg of riboflavin was the smallest amount that would give a discernible yellow fluorescence. The amount of vegetables, even of spinach, that would contain this amount is far too great to be consumed in a reasonable time. Muller reported that children who received milk with some yellow fluorescence did not grow more rapidly than those who consumed milk with blue fluorescence, but the source of the fluorescence was not determined in either case. Because a riboflavin avitaminosis in man has not been reported, it is not known definitely that an increase in the riboflavin content of milk would be of clinical significance.

RIBOFLAVIN CONTENT OF THE EYE

Von Euler and Adler⁴³ reported that the retina of fish eyes contains flavin and suggested that this flavin is of special significance when the light is not intense. The pigment may make it possible to use shorter waves by changing them into green light, for which the eye

has a maximum sensitivity. They had an opportunity to examine a human eye and obtained from it between 0.2 and 0.4 microgram of riboflavin. A codfish eye contains about 50 micrograms, or more than 100 times as much.

RIBOFLAVIN DEFICIENCY AND CATARACT

Cataract in rats is a consequence of vitamin G deficiency,⁴⁴ though some observers report that the condition occurs only in rats that are deprived of the vitamin at an early age.⁴⁵ Day and Langston⁴⁶ observed that a conjunctivitis and keratitis usually developed at 7 or 8 weeks, followed by a dulness of the eyeball and finally a definite opacity. The incidence of the cataract was only a little less than 100 per cent. Cataract was also produced in mice, chickens and monkeys.⁴⁷ Definite evidence that riboflavin is the vitamin G that prevents this type of cataract has been provided by Day, Darby and Langston.⁴⁸

Bourne and Pyke⁴⁹ repeated Day's work, with a maximum incidence of cataract of 31 per cent. Gyorgy⁵⁰ states that cataract was not observed, even though a large number of animals was observed, and in the experience of Richardson and Hogan² this abnormality was rare. The reason for the discrepancies is not apparent, but there is no reason to doubt that under suitable experimental conditions cataract in rats is caused by a deficiency of flavin.

Curiously enough, Mitchell and Dodge⁵¹ have reported that cataract in rats is a consequence of a high lactose diet, but according to Morgan and Cook⁵² the lactose type of dermatitis is not healed by riboflavin.

RIBOFLAVIN, CANINE BLACKTONGUE AND HUMAN PELLAGRA

The hypothesis that blacktongue in dogs is due to a deficiency of vitamin G has not been sustained,⁵³ and more recent studies⁵⁴ show that this disease is not prevented by riboflavin.

The earlier work of Cowgill and his collaborators⁵⁵ on neurologic manifestations in vitamin G (B_2) deficiency was repeated with some modifications, with about the same results. The neurologic changes are described as (a) marked degeneration of the medullary sheaths and axis cylinders of the peripheral nerves, (b) fairly common degeneration of the medullary sheaths of the posterior nerve roots, with less frequent involvement of the anterior roots of the cord, and (c) degeneration of the medullary sheaths and axis cylinders of the posterior columns of the spinal cord.

The authors did not show that riboflavin would prevent the lesions they ascribed to a deficiency of G (B_2) but in a personal communication dated June 30, 1937, Dr Cowgill stated that they were investigating that specific point, and that up to that date riboflavin afforded the same degree of protection against the vitamin G deficiency syndrome as did the liver extract previously used. Rats on diets similar to those employed by Zimmerman and Burack do not develop degeneration of the myelin sheaths in the spinal cord or in peripheral nerves, so dogs and rats seem to respond differently to this deficiency.⁵⁶ Wobach's attitude is apparently expressed in the statement that "the demonstrable nervous lesions of all the deficiency diseases are secondary effects" and "no one vitamin is concerned in the maintenance of myelin."

Sebrell, Hunt and Onstott⁵⁷ confirmed the fact that riboflavin has no therapeutic value in the treatment of blacktongue. It was demonstrated by Richardson and Hogan² that Goldberger's⁵⁸ blacktongue producing diet contains suboptimal amounts of flavin, and Sebrell, Onstott and Hunt⁵⁹ observed that this deficiency may be significant. Thus one dog that had been healed of blacktongue with the filtrate factor collapsed 182 days from the beginning of treatment. During one day 8 mg of lactoflavin was injected intramuscularly and within twelve hours after the first injection the animal was normal. Evidently the dog requires flavin, and a ration could be compounded of natural foodstuffs which is deficient in this substance.

Dann⁶⁰ has reported that riboflavin is ineffective in the treatment of human pellagra. Fouts, Lepkovsky, Helmer and Jukes⁶¹ treated two pellagrins with the filtrate factor of Lepkovsky, Jukes and Krause,⁶² and reported that they were healed. This filtrate factor was prepared from an extract from which lactoflavin had been removed.

Evidently a deficiency of riboflavin is not the primary cause of either pellagra or blacktongue, but it is entirely possible that such a deficiency may be a complication. The diets that are commonly consumed in pellagrous districts are poor sources of riboflavin.

CHICK PELLAGRA

Chicks also develop "pellagra" symptoms⁶³ when reared on rations that have been subjected to prolonged dry heat, but the symptoms are not due to a deficiency of flavin.⁶⁴

RIBOFLAVIN AND PERNICIOUS ANEMIA

Preliminary observations of Strauss and Castle⁶⁵ on the factor that prevents pernicious anemia led them to suggest that the extrinsic factor of pernicious anemia is vitamin B_2 (G) or is closely related to it, but practically all of the more recent reports are negative. Will and Naish⁶⁶ used an extract of egg white as a source of vitamin G and incubated it with normal gastric juice and supplied it to a patient with pernicious anemia, but the outcome was negative. It was shown that a year that egg white contains riboflavin, therefore this newly discovered compound could not be the extrinsic factor. This view has been confirmed by numerous other workers.⁶⁷

Stare and Thompson⁶⁸ administered riboflavin intramuscularly to five patients with pernicious anemia, with no effect. Ashford, Klein and Wilkinson⁶⁹ incubated riboflavin with normal gastric juice, and also with the press juice of hog's stomach, but the hematopoietic activity of the flavin was not increased by the treatment. According to these investigators riboflavin is not the extrinsic factor and is not the antipernicious anemia principle.

RIBOFLAVIN, ADRENAL CORTEX EXTRACT AND IODOACETIC ACID POISONING

Laszt and Verzar⁷⁰ supplied to rats a complete diet, to which had been added 0.02 per cent iodoacetic acid. This was consumed readily, but growth was retarded and after a time the rats became apathetic, there were alterations in the bones, skin and blood, and the adrenals were hypertrophic. If the rats were given 20 micrograms daily of riboflavin-phosphoric acid growth was restored, but riboflavin itself was ineffective. If, instead of the riboflavin ester, the rats received injections of the adrenal cortex extract, growth was again resumed. From these observations the authors concluded that riboflavin must be phosphorylated before it can exercise its normal physiologic function, and that adrenal cortex extract is essential for the phosphorylation process. The toxicity of iodoacetic acid is largely due to the fact that it inhibits this ester formation.

They published additional evidence⁷¹ on this point and suggest that there is a similarity between iodoacetic acid poisoning and the Gee-Herter syndrome (celiac disease)⁷² They believe that in both cases the formation of riboflavin phosphoric acid is inhibited Rudy⁷³ also has studied iodoacetic acid poisoning of rats, but he observed that simple riboflavin is as effective in restoring growth as the phosphoric acid ester The explanation of this discrepancy is not apparent

Adrenalectomy interferes with fat absorption, but Laszt and Verzar⁷⁴ report that absorption is restored to the normal level by administering either adrenal cortex extract or riboflavin phosphoric acid

RIBOFLAVIN IN AVIAN NUTRITION

Lepkovsky and Jukes⁷⁵ reported that chicks which received a basal diet which was deficient in flavin grew slowly, became weak and emaciated and developed diarrhea but did not develop dermatitis Controls that received riboflavin were normal Turkeys did not react in exactly the same way After the eighth day a dermatitis developed which resembled the deficiency disease of chicks first described by Ringrose, Norris and Heuser⁷⁶ If the basal diet was supplemented with riboflavin in the proportion of 2 mg of the vitamin per hundred grams of the diet, dermatitis did not develop, there was no mortality and growth was rapid There was no mention of leg weakness in either chicks or turkeys

Bethke, Record and Wilder⁷⁷ provided baby chicks with a basal ration that was deficient in flavin and observed that it caused a characteristic leg disorder as well as a subnormal rate of growth When the basal diet was supplemented with 40 micrograms of riboflavin every other day the weights were normal and there were no leg disorders The ration used by Bethke and his collaborators was not strikingly different from diet 60 supplied by Lepkovsky and Jukes to turkeys, so it is not clear why the former reported a high incidence of leg weakness and the latter reported none at all

The amount of vitamin G in the ration of laying hens determines, within limits, the amount in the eggs,⁷⁸ and this amount in turn determines the hatchability of the eggs⁷⁹

MISCELLANEOUS

When rats receive diets that are deficient in vitamin G the oxygen uptake of skin cells is lowered⁸⁰ The percentage of dry matter and of total fat in the tissues

is markedly reduced, and that of water correspondingly increased, but these symptoms may be due merely to inanition⁸¹

If the heart is perfused under low oxygen pressure the muscular contractions are weakened⁸² A normal heart beat is restored either by physiologic oxygen pressure or by adding a minute quantity of riboflavin to the perfusion medium

It has been reported⁸³ that strenuous muscular exercise may cause a hypertrophy of the adrenal glands of rats, amounting to 82 per cent The hypertrophy was prevented by feeding large amounts of autoclaved yeast but not by administering riboflavin⁸⁴ It was suggested that the activity of yeast was due to its content of vitamin B₆

A deficiency of vitamin G has little or no effect on the concentration of tissue enzymes⁸⁵

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION

PAUL NICHOLAS LEECH Secretary

PROCAINE-ABBOTT (See New and Nonofficial Remedies, 1937, p 69)

The following dosage forms have been accepted

Ampoules Ephedrine Hydrochloride 2½% and Procaine Hydrochloride 1% 2 cc Ephedrine hydrochloride 2.5 per cent and procaine hydrochloride 1 per cent in chemically pure water to make 2 cc

Ampoules Ephedrine Hydrochloride 5% and Procaine Hydrochloride 1% 1 cc Ephedrine hydrochloride 5 per cent and procaine hydrochloride 1 per cent in chemically pure water to make 1 cc

ADRENALIN (See New and Nonofficial Remedies, 1937, p 222)

Solution of Adrenalin Chloride 1 100 5 cc vials—A solution containing 1 part adrenalin (as adrenalin chloride) in 100 parts of physiological solution of sodium chloride preserved by the addition of 0.5 per cent of chlorotone and not more than 0.1 per cent of sodium bisulfite

Actions and Uses—Injections of solutions of epinephrine (1:1000) are known to be useful in the treatment of severe attacks of bronchial asthma Recent evidence indicates that the oral inhalation of a solution of epinephrine ten times stronger than those used by hypodermic injection gives relief in acute attacks of bronchial asthma when other measures fail The physician should familiarize himself with the procedure before employing it in the treatment of his patients It is absolutely essential that such treatment be instituted under the supervision of the physician and the patient warned of the dangers of using a solution of such strength carelessly It is also necessary that the atomizer or nebulizer which is used in the administration of such solutions produce a fine mistlike spray free from minute droplets Every precaution must be taken to avoid confusion between this solution (1:100) and the official 1:1000 solution of epinephrine hydrochloride since the 1:100 solution is not suitable for hypodermic use and should never be employed in that manner

Dosage—A definite dosage cannot be stated for the use of this preparation It is obviously essential that the amounts used not exceed the minimal amount which will give effective relief It is best to start with a single compression of the bulb of the atomizer or nebulizer until it is determined what dosage is adequate and safe Its use should not be repeated until several minutes have passed so that the full effect of the inhalation can be observed before additional amounts are used

SULFANILAMIDE-P D & CO (See THE JOURNAL, Nov 6, 1937, p 1543)

ELEVEN DEATHS FROM A CANCER TREATMENT

The complete story of the tragedy in Orlando, Fla., reported in a special article¹ in this issue of THE JOURNAL, cannot yet be written. Enough facts are already available, however, to warrant a reemphasis of the warning that THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has made repeatedly against the use in medical practice of unstandardized, unestablished and uncontrolled methods of treatment.

In October 1935, when the "ensol" treatment was launched from Kingston, Ont., with what appeared to be carefully planned publicity in the newspapers, THE JOURNAL issued a warning to the effect that the product was being developed under uncontrolled conditions and that its exploitation would inevitably lead to grief for those concerned. Now almost three years have passed. Evidence resulting from experiments on animals indicates that the method is without established value. The clinical evidence has been uncontrolled. There is really no good clinical evidence that this method has any beneficial effect in the treatment of cancer. Nevertheless a considerable number of doctors in various parts of the United States have used a product of this type in the treatment of cancer and it is obvious that one at least has come to grief.

As we go to press, it seems that the Biochemical Research Foundation of the Franklin Institute of Philadelphia prepared the product called R or Rev, which caused the deaths of the patients in Orlando, Fla. It seems likely that batch 152 was prepared on a Friday, some of it permitted to stand over Saturday and Sunday, and then sterilized on Monday. If the tetanus organism was present in the product it would have had two days in which to develop the toxin, so that when the product was sterilized on Monday a sufficient amount of tetanus toxin was present to cause death. These possibilities remain to be confirmed by more evidence—but certainly enough evidence is available to warrant the suggestion.

At present there are being exploited to the American people a half dozen or more treatments of cancer that

are in no way established as actually of value in the treatment of that condition. Time is the great test of cancer cures. Many of these methods of treatment have already been before the public long enough to indicate that they are absolutely worthless. Enough is now known about the nature of cancer to indicate that the value of a cancer remedy cannot be established by sending it at random to physicians scattered all over the country, who use it in practice for a fee. The development, exploitation and promotion of "ensol" and of its progeny "R" have been unscientific, unethical and unwarranted. Some means must be found to protect the people against their use as guinea pigs in this kind of experimentation.

ENDOCREME—A COSMETIC WITH A MENACE

In current periodicals, especially those directed to women, there have been appearing the advertisements for a product called Endocrine. In some of the latest copy which, incidentally, bears the approval of the Good Housekeeping Bureau, appear the following statements:

Endocrine contains a counterpart of the natural bodily element which helps account for that pink freshness of a youthful skin. This substance is known to the medical world as es-tra-di-ol, and Endocrine is the only cosmetic which contains es-tra-di-ol. It helps replenish the supply of the very substance which your skin may lack.

Endocrine, therefore, is more than "just a face cream." It is an active, vital cosmetic which begins its work with the substructure of the skin. In later life, the skin tends to fall into lines and wrinkles because the tissues underneath the skin sag. When Endocrine firms and tones these underlying tissues, the skin is smoothed out again, pores decrease in size and lines begin to disappear.

Not only is the product widely advertised, it is also sold over the counter in many leading department stores, drug stores and beauty shops. For more than a year this product, manufactured by the Hirestra Laboratories, Inc., of New York, has been offered to the public without a word of warning that it may be a potential menace to health and life. Now, on the basis of available evidence, which the manufacturer should have had before the product was sold openly to the public, THE JOURNAL is warranted in warning users of this product that its indiscriminate use may lead to dangerous consequences, that it possesses the potentiality of bringing about serious changes in the genital and reproductive organs of women, that it may induce changes in the breasts, and that there is, in addition, to possible disorganization of the menstrual cycle, the potentiality of the production of cancer.

Endocrine is claimed to contain 0.625 mg of estradiol per ounce. The purchaser of this preparation is told to apply one-half teaspoonful to the face, neck, arms and hands every night and is cautioned against omitting treatment for a single night if the best results are to be obtained. In one of the early advertisements

¹ Eleven Deaths from a Cancer Treatment this issue p 1183

for this product, the statement is made "There is no danger of overapplication. The skin absorbs only as much as it needs of the vitalizing hormone contained exclusively in Endocrine, the only hormone of its type which has been scientifically proved to be absorbed by the skin." Of course, it has been known for some time that estrogens may be absorbed from the skin and may thus exert systemic effects.¹ Nevertheless, it is claimed that Endocrine acts on the skin alone and has no effect on internal organs.

From many sources now comes scientific evidence indicating the potentiality for serious harm that lies in the persistent use of the product called Endocrine. At the University of Chicago Prof. Carl R. Moore² has been making some experiments which are to be presented before a national scientific organization within a few weeks but which have been made immediately available to *THE JOURNAL* so that this warning might be issued. Samples were purchased from a leading department store in the city of Chicago. The product is available in department stores and drug stores everywhere at the price of \$3.50 for a two ounce jar.

One-half teaspoonful of the ointment was found to weigh about 1.82 Gm., on the basis of the claimed content of estradiol, this quantity of cream represents approximately 0.04 mg. of estradiol. About one-fifth this dose, 0.372 Gm. of Endocrine (0.0082 mg. of estradiol), was rubbed daily on the back of the neck (previously shaved) of spayed female rats, young normal male rats and normal male guinea pigs for periods of from two to twenty-one days. The Chicago investigators found that this amount of Endocrine (1) induces an estrous reaction in castrated female rats in forty-eight hours, (2) maintains normal uterine weight in such rats, (3) induces growth of mammary glands in normal male guinea pigs, and (4) exerts profound degenerative changes in the testes of normal young rats. They believe that continued application of Endocrine to large areas of skin in normal women may have serious consequences in possible disorganization of the menstrual cycle.

Inunction of an ointment containing a potent steroid may be even more effective in producing systemic effects than parenteral injection, indeed, Moore and his associates have found the former to be the more effective method of administering androgens (closely related chemically to the estrogens) owing apparently to slower absorption and hence better utilization. Zondek^{3c} found that a given amount of estrogen inunction into the skin was as effective in the production of mammary growth as the same amount injected subcutaneously. However, to produce an estrous effect seven times as much was necessary by cutaneous administration. Thus, it may be seen that daily

inunction of Endocrine may actually lead to as great a systemic effect, at least with respect to certain organs, as parenteral injection of an equal amount of estrogen.

While the dosage of estradiol used in the experiments cited represents a much larger amount per unit of body weight than that recommended for the human being, one must consider both the enormously larger surface area to which the ointment is applied in women as well as the much longer period of administration. Further, the known proliferative effects of estrogens on tissues with which they come into direct contact in high concentration leads to apprehension as to the probable result should Endocrine be applied regularly to a potentially neoplastic pigmented mole such as occurs frequently in the human skin.

Lesions of various types and in various organs have been produced in animals through the use of large doses of estrogen over long periods.³ Among these carcinoma of the breast appears to be the most common, but other tissues may also be affected. Two years ago, Gardner and his co-workers⁴ reported the production of sarcoma at the site of injection of an estrogenic preparation and recently these investigators⁵ have produced carcinoma of the cervix in mice. In an article in this issue of *THE JOURNAL* Drs. Gardner, Allen, Smith and Strong in the department of anatomy of Yale University at New Haven found that a tumor of the cervix of the uterus of large size developed in a mouse receiving estradiol and was successfully transplanted into male and female mice of the same inbred strain. They believe also that smaller growths observed in eighteen other mice which had received this substance are probably precancerous growths or early cancers. Incidentally, the injection of the oil used as a solvent for the estradiol benzoate did not produce any such changes.

Shortly after Endocrine was first launched, a periodical called *Drug and Cosmetic Industry*⁶ itself issued the following warning:

We have published little or nothing on hormones in cosmetics since we are, at least for the present, opposed to the use of these materials in cosmetics until knowledge is fuller these products should not be administered indiscriminately and without supervision.

Apparently, even experts in the cosmetic industry had misgivings!

Estrogen, as has already been well established, has definite uses in medicine when properly employed under controlled conditions. Now evidence becomes available that this endocrine principle, like all other potent endocrine substances, is a two-edged sword capable of remarkable achievements when properly used and

dangerous when carelessly employed. The continued reckless and indiscriminate use of this substance in a cosmetic cream is certainly unwarranted until it has been proved beyond the shadow of a doubt that the menace clearly established in animals does not likewise prevail in human beings.

CYSTINE AND METHIONINE

Man's knowledge of sulfur dates back to the time of the ancients. The essential nature of this element and its metabolic significance constitute an important chapter in the history of physiologic chemistry. Most of the sulfur that is concerned with metabolism enters the body in organic combination, largely as protein. Although cystine, the first sulfur-containing amino acid known to exist in proteins, was discovered by Wollaston in 1810 in a renal calculus, its presence in protein was not demonstrated until eighty years later. In 1915 Osborne and Mendel reported the results of experiments which are interpreted to mean that cystine is an indispensable amino acid, i. e., it must be provided in the food if physiologic well being is to be supported.

In 1921 Mueller¹ discovered a second sulfur-containing amino acid in the digestion products from casein, this compound was subsequently named methionine. It is a methiol derivative of butyric acid and essentially a homologue of cystine. Eleven years after the discovery of methionine, Jackson and Block² showed that an experimental purified ration, too poor in cystine to permit normal growth in young rats, could be made adequate in this respect by the addition of methionine. This demonstration of apparent interconvertibility of cystine and methionine raised the question of the essential nature of both these amino acids in nutrition. Later, on the basis of studies of the behavior of the sulfur-containing amino acids in a cystinuric patient, Brand and his associates³ questioned the indispensability of cystine while placing methionine in this category.

Recently new experimental devices have been employed in studies designed to test further the problem of the nutritive significance of cystine and methionine. Employing a highly purified experimental diet containing practically all the nitrogen in the form of a known mixture of amino acids, Womack, Kemmerer and Rose⁴ proved that increase in body weight of young rats was secured when methionine and cystine together or when methionine alone was present but that failure resulted with cystine alone. Again, White and Beach⁵ using arachin, a protein from the peanut which

contains adequate cystine but is deficient in methionine, have demonstrated that under these conditions methionine, but not cystine, will support progressive increase in body weight of experimental animals. Although these studies show that methionine is indispensable apart from its relationship to cystine, it appears from the available evidence that the latter can serve to stimulate growth when methionine is present in sub-optimal quantities.

The foregoing conclusion, of fundamental significance in the biochemistry of proteins, is a triumph of skillful and critical work in the fields of nutrition and organic chemistry. Although there doubtless are other as yet unidentified sulfur-containing components of the protein molecule,⁶ the recent advances in the knowledge of the sulfur-containing amino acids of proteins have served to further the establishment of protein metabolism on a simpler and more rational basis.

Current Comment

CARBON MONOXIDE AND THE ABILITY TO DRIVE AUTOMOBILES

The interiors of about 5 per cent of automobiles tested on the highways contain sufficiently high concentrations of carbon monoxide to produce symptoms such as dizziness or collapse. Forbes and his colleagues¹ devised two sets of experiments to test the driving ability of persons subjected to an atmosphere containing enough carbon monoxide to produce degrees of blood saturation comparable to those obtaining in drivers. In the first experiments, about 900 cc of pure carbon monoxide was put into 1,000 liters of air in a large bag. The subjects breathed this for an hour through a mouth piece. Blood samples were taken before the exposure, after thirty minutes of exposure and at the end of the experiment. The inspired and expired air was analyzed and the volume of respiration was measured, together with the respiratory rate, the pulse rate and the concentration of the blood sugar. The second set of experiments was made in substantially the same manner except that automobile exhaust gases were used in place of pure carbon monoxide. The tests used to determine the effect on driving ability were the time taken to remove the foot from the accelerator, the time to push down a brake pedal after a red light was flashed on, perception of depth, ability to see dim objects at the side of a bright light, ability to see the approach or recession of bright objects, and accuracy of steering. In the second group of experiments the steering test and the test with the bright light were abandoned. A coordination testing device was substituted. In eleven experiments of this nature on eight normal men it was found that their performances in simple tests of reaction time, binocular

vision and similar trials were unaffected by breathing carbon monoxide until their blood was 30 per cent or more saturated. At 45 per cent saturation the quality of performance was only slightly impaired. Subjectively the persons tested felt normal up to 30 per cent saturation, but the two whose blood reached a 45 per cent saturation appeared and felt unequal to driving a car because unable to think of many things at once. The pulse rate, respiratory rate and concentration of blood sugar also remained unchanged up to 30 per cent saturation. It was agreed, however, that a test was needed to show the ability to attend to several things at once and that there might be some impairment with low saturation which could not be demonstrated by tests applied.

THE MORE ABUNDANT DIET

Current emphasis on the essential components of diet has perhaps caused some neglect of the part which quantity plays. McLester,¹ in an address given before the American Dietetic Association in Richmond last October, spoke feelingly of the illnesses that have been made worse by the injudicious restriction of food and of the benefit that may be reasonably expected from the administration of a more abundant diet. First among those diseases unfavorably affected by dietary restriction is typhoid. Today, although still without specific treatment typhoid patients, in contradistinction to past procedure, are given liberal rations with graphically demonstrable effect on the case fatality rates. Similarly and only slightly less striking are the results in Bright's disease. The discovery that low plasma protein is a salient feature of glomerular nephritis, and the subsequent introduction of liberal protein rations, have no doubt saved many patients with nephritis. A similar story is being written with essential hypertension and nephrosclerosis. Although neither is primarily a disease of the kidneys protein restriction probably has been carried too far in the past. Even more important than treatment is the adequacy of diet in the prevention of disease. The prevention of infection by dietary means has been predicated repeatedly during the last few years. In fact, liberal amounts of foods rich in vitamins are almost certainly one factor in the protection against infection. Nutritive deficiency, McLester believes, is not infrequently the underlying cause of such disabilities as lack of appetite, digestive disorders, vague pains and discomforts unassociated with other organic disease. Such symptoms are seen particularly among women, young and old, irrespective of economic status, who would remain stylishly thin, and among food faddists and those who, because of some digestive disorder, have been caught in a vicious circle of dietary restriction. The ideal diet, therefore, is one which both in sickness and in health will meet but not exceed the individual's caloric needs and which will provide a liberal excess of duly calculated requirements of nutritive essentials especially proteins and vitamins.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARKANSAS

State Medical Meeting at Texarkana—The sixty-third annual session of the Arkansas Medical Society will be held at the Grim Hotel, Texarkana, April 18-20, under the presidency of Dr Oscar J T Johnston, Batesville. The following scientific program has been arranged:

Dr John H J Upham Columbus Ohio President American Medical Association Clinical Implications of Some Recent Studies in Gastric Motility
Dr M Herbert Barker Chicago Phases of Renal Edema and Their Treatment
Dr John Shelton Horsley Richmond Va The Symptoms Diagnosis and Treatment of Cancer of the Stomach
Dr Charles R Gowen Shreveport La Collapse Therapy in Pulmonary Tuberculosis
Dr Alexis F Hartmann St Louis Present Status of Sulfanilamide Therapy for Severe Infections in Infants and Children
Dr Don H O Donoghue Oklahoma City Fractures of the Elbow
Dr Clarence B Erickson Shreveport Treatment of Some Common Skin Diseases
Dr Arthur G Schoch Dallas Diagnosis and Treatment of Early Syphilis
Dr Wiley R Buffington New Orleans Detached Retina
Dr Nesbitt L Miller Oklahoma City Allergy in General Practice
Dr Frederick J Taussig St Louis Controlling the Size of the Family
Dr Roland M Klemme St Louis Diagnosis and Treatment of Brain Tumors

The breakfast for past presidents will be held Wednesday morning and the conference of county society secretaries to be addressed by Dr Shade D Neely, Muskogee, Okla., will take place Monday morning. There will be a golf tournament Tuesday at the Texarkana Country Club. The Arkansas State Pediatric Society will meet Monday at the Grim Hotel and the fourteenth annual meeting of the Woman's Auxiliary will be held at the McCartney Hotel Texarkana. Speakers at a public session will include Dr Horsley on 'The Menace of Cancer' and Dr Upham, 'Present Day Problems in the Medical Profession'.

CALIFORNIA

Society News—Dr Alvin G Foord, Pasadena addressed the San Diego County Medical Society March 8 on 'Classification and Diagnosis of Anemias'.—Dr Pierce C Barrette, San Jose, among others, addressed the Santa Clara County Medical Society recently on 'Effectiveness of Water Soluble Iodine in Reversing the Wassermann Reaction' and Dr Marvin B Morehead 'Internal Pneumolysis in the Treatment of Pulmonary Tuberculosis'.

Study of Hospitalization of Insane—Five physicians have been appointed to a committee to aid the state interim committee on state hospitals, authorized by the legislature to study hospitalization of the insane according to the *Oakland Tribune*. Those named on the advisory committee are Drs Glenn E Myers Compton Forrest N Anderson Los Angeles, Benjamin W Black Oakland Edward W Twitchell, San Francisco, and Clifford W Mack, Livermore.

CONNECTICUT

Diagnostic Clinics for Crippled Children—The first crippled children's diagnostic clinic under the Connecticut State Plan for Crippled Children Services was held at the Windham Community Memorial Hospital Willimantic February 3, and the second at the William W Backus Hospital Norwich February 9. Others were held February 24 at Danbury Hospital Danbury March 2 at Newington Home for Crippled Children, Newington, and March 11 at Stamford Hospital, Stamford.

Dr Steiner Honored—The Hartford Medical Society gave a dinner February 7 in honor of Dr Walter R Steiner who has served as librarian for thirty-five years and for whom the society recently named its library. Dr Thomas Archibald Malloch librarian of the New York Academy of Medicine, New York gave an address on 'Medical Libraries'. A portrait of Dr Steiner was presented to the society and unveiled. Dr Steiner was president of the Medical Library Association from 1931 to 1933 secretary of the Connecticut State Medical Society from 1905 to 1912 chairman of its council 1929-1933 and president 1934-1935. He was president of the Hartford

Medical Society in 1929 and of the American Clinical and Climatological Association, 1934-1935. Except for the sessions of 1926 and 1928, Dr Steiner has been a member of the House of Delegates of the American Medical Association since 1919.

ILLINOIS

Committee to Standardize Diagnostic Laboratory Procedures—The appointment of a special state committee on standardizing diagnostic laboratory procedures throughout Illinois has been announced by the state department of health. Members include

Dr Alexander A. Day, professor of bacteriology, Northwestern University Medical School, Chicago.

Dr Irving H. Neece, district counselor of the seventh district of the Illinois State Medical Society.

Dr Lewis R. Hill, pathologist, Chicago.

Dr John L. White, chief of the diagnostic laboratories, Chicago City Health Department.

Dr Lloyd Arnold, professor of bacteriology and public health, University of Illinois College of Medicine, Chicago.

Reuben Kahn, D.Sc., Ann Arbor, Mich., consultant.

The first meeting of the committee was held March 15. Its function will be to work out standards for the approval of diagnostic laboratories in the state and to act as referee in cases of dispute concerning the approval of local laboratories.

Chicago

Meetings of Chicago Medical Society—Dr Olm West, Secretary and General Manager, American Medical Association, will address the Chicago Medical Society at a special meeting April 10 in the Goodman Theater on "Medicine and the Government." Dr Logan Clendenning, Kansas City, Mo., clinical professor of medicine, University of Kansas School of Medicine, will deliver a public lecture sponsored by the medical society at the Goodman Theater April 13 on "The Care and Feeding of Humans."

Bertha Kaplan Spector Dies—Bertha Kaplan Spector, Ph.D., research associate in medicine at the University of Chicago and well known for her work in amebic dysentery, died March 26 in Billings Hospital of Hodgkin's disease, aged 41. Dr Spector, who took her doctorate at the university in 1931, had been on the staff since July 1, 1929, working under a special grant of the Douglas Smith Foundation in the Department of Medicine, Division of Biological Sciences. She had served as research assistant at the Bussey Institute of Harvard University, bacteriologist at the U. S. Army Base Hospital, Fort Riley, Kan., the U. S. Veterans' Administration Facility, Hines, Ill., Cook County Hospital and on the staff of the University of Illinois College of Medicine. From 1934 until her death she was protozoologist of the U. S. Public Health Service. She assisted in the investigation of an outbreak of amebic dysentery in Chicago in 1926 and did important work in the epidemic in 1933. She also assisted in a study of dysentery in New Mexico made by the National Institute of Health, U. S. Public Health Service, in 1936 and 1937, among certain groups of American Indians. In 1929 Dr Spector received the Beaumont Prize from the University of Illinois for her research on diseases of the gastro-intestinal tract.

IOWA

Society News—Dr Albert Graeme Mitchell, Cincinnati, discussed "What I Do Not Know About Endocrinism" before the Linn County Medical Society March 31 in Cedar Rapids. The society was addressed March 3 by Drs Nathaniel G. Alcock, Iowa City, on "Malignancy of the Kidney," Paul F. Stookey, Kansas City, Mo., "Staphylococcus Septicemia," and James H. Allen, Iowa City, "Staphylococcus Conjunctivitis."—Dr Frank R. Peterson, Iowa City, addressed the Black Hawk County Medical Society in Waterloo February 15 on "Cancer of the Colon and Rectum."—At a meeting of the Crawford County Medical Society in Denison February 15 Dr John Harry Murphy, Omaha, discussed "Tuberculosis in Children."—Drs Arthur Stendler and Joseph H. Wolfe, Iowa City, presented a symposium on fractures before the Johnson County Medical Society, Iowa City, February 2.

KANSAS

Educational Program on Tuberculosis—The Kansas Tuberculosis and Health Association in cooperation with the Kansas State Board of Health and the committee on the control of tuberculosis of the state medical society will sponsor an educational program on the control of tuberculosis, April 18-22. Lectures will be delivered before professional and lay audiences, the speakers to be Drs Paul A. Teschner, Chicago, assistant director, Bureau of Health and Public Instruction, American Medical Association, and Hyman I. Spector, chief of the chest clinic and instructor in internal medicine, St. Louis

University School of Medicine, St. Louis. Dr Teschner will address the profession on "Cases, Contacts and Cooperation" and lay audiences, "Fighting Tuberculosis to a Finish." Dr Spector, as the clinical speaker, will discuss subjects pertaining chiefly to the early diagnosis of pulmonary tuberculosis. Tentative dates and places of meetings are Leavenworth April 18, Ottawa April 19, Parsons April 20, Wichita April 21 and Russell April 22. It is planned to hold the session for the public in the afternoons, when the film "Behind the Shadows" will be shown.

LOUISIANA

Shell Oysters Must Be Tagged—In accordance with a recently revised federal law, the Louisiana State Board of Health ordered that after March 1 all shipments of shell oysters without identification tags be stopped. The purpose of the tagging is to facilitate the tracing of oysters to the bedding grounds where they are grown in case they cause any illness when eaten. Tags may be obtained by the oyster fishermen from the dealers to whom they ship.

Sentenced for Posing as Physician—D. T. Garrison Meridian, Miss., was sentenced by Judge Ben C. Dawkins in federal court, Shreveport, March 2, to serve three years in the El Reno, Okla., federal penitentiary when he was found guilty of posing as a government physician, according to the Shreveport Times. Garrison is said to have defrauded Negroes of DeSoto Parish by selling them a concoction which he claimed was a medicine of "great curative powers." The mixture was said to contain aloes and peppermint, which Garrison sold in bottles at \$4.50 each, making a profit of \$4.35 on each sale. The testimony disclosed that Garrison claimed to be a chiropractor, stating that he received a diploma from a chiropractic school in Chicago twenty-three years ago.

MASSACHUSETTS

Society News—Dr John T. B. Carmody, among others, addressed the Worcester District Medical Society March 9 on "Indications for Surgical Intervention in Head Injuries."—The Brookfield Medical Club was addressed March 16 by Dr George L. Schadt, Springfield, on "Modern Laboratory Technique for the Practicing Physician."—Dr Joseph C. Aub Boston, discussed "Endocrine Disorders of Childhood" before the New England Pediatric Society February 25.—At a meeting of the Harvard Medical Society, Boston March 8 Dr John P. Peters, New Haven, Conn., spoke on "Exchange Between Cells and Interstitial Fluid."—The New England Heart Association was addressed February 28 in Boston, among others, by Drs Burton E. Hamilton on "Prognosis of Adult Women with Mitral Stenosis" and Lewis M. Hurvith, "Congestive Failure on Using Digitalis."

MICHIGAN

Personal—Dr Reuben J. Harrington, Muskegon has been appointed health officer of Muskegon County.—At a meeting of the Dickinson-Iron County Medical Society in Crystal Falls, February 9, Dr Joseph A. Crowell, Iron Mountain, was made a member emeritus and Dr Edward P. Lockhart, Norway, an honorary member.—Dr Luther Peck, health officer of Plymouth, was presented with the community service award by the Rotary Club of Plymouth, February 25, in recognition of his thirty-five years' service to the city. Dr Peck has been health officer since 1935 and also held the position many years ago.

Annual Clinic—The Ingham County Medical Society will hold its annual clinic at the Hotel Olds, Lansing, April 28. The following will participate:

Dr Henry G. Poncher, Chicago, Clinical Implications of Recent Advances in Nutrition in Infancy and Childhood.
Dr Edward H. Rynerson, Rochester, Minn., Protamine Insulin.
Dr James M. Pierce, Cincinnati, The Management of Abnormal Labor.
Dr Frederick Christopher, Evanston, Ill., Diagnosis and Treatment of Right Lower Quadrant Lesions.

Mr C. O. Otto, secretary, Lansing Chamber of Commerce will be the toastmaster at the annual banquet and Dr Fred Erick A. Collier, Ann Arbor, the speaker.

NEBRASKA

Society News—At a meeting of the Third Council District in Pawnee City recently the speakers included Drs Raymond L. Traynor, on "The Diarrheas," William J. McMartin, Omaha, "Use of Sulfanilamide in Urinary Tract Infections," and Frank P. Murphy, Omaha, "Management of Occiput Posterior Presentation."—The Southwest Medical Society met February 12 in McCook, with the following speakers:

ers, all of Omaha Drs Herbert H Davis, on "Endocrinology Related to Physiology", Frank Lowell Dunn, "Treatment of Arthritis," and Abiam E Bennett 'Prevention of Neurosyphilis'—Clarence C Little Sc D, Bar Harbor, Maine, addressed the Omaha-Douglas County Medical Society, March 10, on 'The Cancer Problem'

NEW JERSEY

State Society President Honored—Dr William G Herrman, Asbury Park, president of the Medical Society of New Jersey, received a medal of honor from Rutgers University, New Brunswick, at a ceremony on Alumni Day February 22 Dr Herrman graduated from Rutgers in 1912 The president of the university, Robert C Clothier, Litt D, paid tribute in his citation to Dr Herrman's services, both to the university and to the medical profession

NEW YORK

Personal—Dr Evelyn F H Rogers, Bedford Hills has been appointed epidemiologist-in training in the state department of health and after a year's study will be assigned to the division of maternity, infancy and child hygiene

Society News—Dr James J Short New York, addressed the Dutchess County Medical Society, February 9 on 'Studies in Obesity'—Dr Frederick A D Alexander, Albany, addressed the Montgomery County Medical Society February 16 at Amsterdam on 'Use of Common Depressant Hypnotics for Preanesthesia and Postanesthesia'—At a meeting of the Niagara County Medical Society, February 8, Dr Clayton W Greene, Buffalo, spoke on 'What Can We Do for Angina Pectoris and Coronary Occlusion'—A group of pathologists met in Albany February 26 to organize the New York State Society of Pathologists

Typhoid Carriers Under Supervision—The state department of health recently reported that 398 typhoid carriers are now under supervision in upstate New York, exclusive of those in state institutions, eighteen more than the number reported for 1936 During the year forty-three carriers were added to the list and thirty were removed Twenty-nine were discovered through epidemiologic study of outbreaks or sporadic outbreaks Of those removed from the list twelve died and ten moved from the state Seven were released after submitting the required number of negative specimens Three outbreaks during 1937 were traced to previously unrecognized carriers

New York City

Long Island Alumni Meeting—The Alumni Day of Long Island College of Medicine will be held April 30 at the college and hospital Dr Albert F R Andresen will speak on "Gastrointestinal Carcinoma" and Capt Richard C Holcomb, U S Navy The Evolutionary Perspective of Syphilis The annual dinner will be held at the Columbus Club, with Mayor Frank Hague of Jersey City as the speaker

Conference on Tuberculosis—The fourteenth clinical session of the Tuberculosis Sanatorium Conference of Metropolitan New York will be held April 13 at Cornell University Medical College The speakers will be Drs Emmanuel W Billard on 'Hematogenous Tuberculosis', Clara Regina Gross, 'Postinstitutional Supervision of Cases', Arthur B Robins, 'Mass Case Finding, and Herbert R Edwards Tuberculosis Program of the Department of Health'

Third Teaching Health Center Opened—The Kips Bay-Yorkville Health Center, the third of five to be operated by the city in conjunction with the five medical schools of the city, was opened March 16 Speakers at the ceremonies were Mayor La Guardia Dr John L Rice, health commissioner Dr Livingston Farrand president emeritus and Edmund Ezra Day, Ph D, president of Cornell University with which the new center will be affiliated The four story building was built with PWA funds at a cost of \$314,000 and the site was made available to the city by the Rockefeller Foundation and the Milbank Memorial Fund

Dr Keyes Awarded the Snow Medal—Dr Edward L Keyes professor of clinical surgery Cornell University Medical College received the first William Freeman Snow Medal for distinguished service in the field of social hygiene at the annual dinner of the American Social Hygiene Association February 3 at the Hotel Astor This award was established at a testimonial dinner Oct 1, 1937, to Dr Snow general director of the American Social Hygiene Association Dr Keyes was president of the association from 1923 to 1935

He was graduated from Columbia University College of Physicians and Surgeons in 1895 and has been a teacher of urology at Cornell since 1904, except 1910-1911 when he was professor of urology at Bellevue Hospital Medical College He has been president of the American Association of Genito-Urinary Surgeons, American Urological Association and the International Urological Association

NORTH CAROLINA

Tumor Clinic at Wake Forest—The cancer committee of the Medical Society of North Carolina will sponsor a tumor clinic at the Wake Forest College School of Medicine, Wake Forest, April 14-15 The speakers will be Drs Charles F Geschickter Baltimore, J Grafton Love, Rochester, Minn, and Max Cutler, Chicago

Pneumonia Control Commission—The North Carolina State Board of Health, with the cooperation of the Medical Society of North Carolina and the Duke University School of Medicine, has established a pneumonia commission with Dr Hubert B Haywood, Raleigh, as chairman One of its first activities was a week of laboratory instruction for technicians of the state at Duke University in January, attended by more than sixty technicians

Society News—Dr B B Vincent Lyon, Philadelphia, addressed the Rowan County Medical Society, Salisbury, February 3, on "Diagnosis and Medical Management of Gallbladder Diseases"—Dr Wingate M Johnson, Winston-Salem, N C, addressed the Guilford County Medical Society, Greensboro, February 3, on "Osteomyelitis and Staphylococcus Septicemia"—Dr Wilson Pendleton, Asheville, addressed the Buncombe County Medical Society, Asheville, January 17, on 'The Allergic Patient'—Drs Forrest D Edwards, Lenoir, and Lawrence M Fetner, Lenoir, addressed the Catawba Valley Medical Society, Hickory, January 13, on "Pneumonia" and Superficial Roentgen Therapy, Its Uses and Abuses," respectively

OHIO

Society News—Dr Emmerich von Haam, Columbus, addressed the Montgomery County Medical Society, Dayton, February 18, on 'Diagnosis of Venereal Lesions'—Dr Jennings M King, Pittsburgh, addressed the Columbiana County Medical Society, Lisbon, February 8 on "Arthritis with Special Attention to Orthopedic Treatment"—Dr William W Weiss, Piqua, addressed the Miami County Medical Society in Troy February 4 on cancer of the breast—Dr Miles Tischer Hoerner Dayton, was the speaker at a meeting of the Preble County Medical Society, Eaton, February 16, on diagnosis and treatment of jaundice—Dr Harry V Paryzek, Cleveland, discussed 'Dangers of Socialized Medicine' before the Lorain County Medical Society, Elyria, February 8—Dr Harold C Weisenbarger, Lima, addressed the Mercer County Medical Society, Rockford, February 17, on 'Kidneys and Their Diseases'

OKLAHOMA

Graduate Course in Obstetrics—The committee on post-graduate teaching of the Oklahoma State Medical Association has arranged a course in obstetrics to be given throughout the state There will be ten lectures and clinics lasting two hours once a week Dr Edward N Smith, Jersey City, N J will be the instructor Financial assistance has been furnished by the Commonwealth Fund and the state department of health The fee will be \$5 for the course

PENNSYLVANIA

State Tuberculosis Meeting—The forty-sixth annual meeting of the Pennsylvania Tuberculosis Society was held in York, February 15-16 At a special medical session the speakers were Homer L Sampson, D Sc Saranac Lake N Y, on 'Place of the Roentgen Ray in Tuberculosis' and Dr James Burns Amberson Jr, New York on "Pneumothorax" Dr William Devitt, Allenwood, was elected president

Philadelphia

Society News—Among speakers at a meeting of the Philadelphia Pediatric Society March 8 were Drs Thomas A Shallow, on 'Foreign Bodies in the Intestinal Tract of Children' David M Davis Results in Treatment of Pyelitis Resistant to Medical Management and John W Holmes Summary of Results in Treatment of Gonorrheal Vaginitis with Sulfanilamide—Drs William Edward Chamberlain and Temple S Fay among others addressed the Philadelphia Urological Society February 28, on 'Painful Urinary Backflow'

and 'Role of Suprapubic Cystostomy in Cord Bladder' respectively—Dr Warfield T Longcope, Baltimore, delivered the nineteenth Nathan Lewis Hatfield Lecture of the College of Physicians of Philadelphia, March 2, on "Pathogenesis and Treatment of Streptococcal Infection"—Speakers before the Obstetrical Society of Philadelphia, March 3, were Drs Clayton T Beechan, on "Postpartum Hemorrhage as a Cause of Death", Ralph M Tyson, "Seven Years' Study of Infant Mortality," and James P Lewis, "Treatment of Myoma Uteri"—At a meeting of the Philadelphia Roentgen Ray Society, March 3, Drs Gilson C Engel, Hans May and Robert Shoemaker presented a paper on 'Use of the Two-Plane Direction and Range Finder for Internal Fixation for Fractures of the Neck of the Femur' and Dr Jacob Gershon-Cohen 'Effect of Osmotic Changes in the Duodenum on Gastric Motility'

Pittsburgh

Annual Meeting—Dr Irvin Abell, Louisville, Ky, President-Elect of the American Medical Association, will address the Allegheny County Medical Society at its annual meeting and banquet April 19 at the William Penn Hotel. At the afternoon scientific session speakers will be

- Dr Charles W Mayo, Rochester, Minn, 'A Surgical Viewpoint of Duodenal Ulcer'
 - Dr Udo J Wile, Ann Arbor, Mich, 'Syphilis in Relation to Surgical Problems'
 - Dr Chevalier Jackson, Philadelphia, 'Pulmonary Pathology with Special Reference to Its Study in the Living'
 - Dr Frank E Adam, New York, 'Diagnosis and Treatment of Breast Tumors'
 - Dr Roy W Scott, Cleveland, 'Clinical Aspects of Arteriosclerosis'
- Mayor Scully will be a speaker at the banquet

TENNESSEE

State Medical Meeting at Nashville—The one hundred and fifth annual meeting of the Tennessee State Medical Association will be held in Nashville April 12-14 with headquarters at the Noel Hotel. Guest speakers are announced as follows:

- Dr James W Bruce, Louisville, Ky, 'Behavior Problems in Children'
- Dr Gershon J Thompson, Rochester, Minn, 'Transurethral Prostatectomy'
- Dr John Zahorsky, St. Louis, 'The Newborn Baby in the Hospital'
- Dr Arthur W Erskine, Cedar Rapids, Iowa, 'Modern X-Ray Treatment'
- Dr H Earle Conwell, Birmingham, Ala, 'The Internal Fixation of Fractures of the Neck of the Femur'
- Dr Frank E Whitacre, Chicago, 'Diagnosis and Treatment of the Non-convulsive Toxemia of Pregnancy'

At an evening meeting Dr Irvin Abell, Louisville, President-Elect of the American Medical Association, will deliver an address on 'Medicine and the Changing Social Order' and Dr George C Williamson, Columbia, will deliver his address as president of the state association. A symposium on traumatic cases has been arranged in cooperation with the section on railway surgery with the following speakers: Drs William J Sheridan, Chattanooga; Jarrell Penn Knoxville; George K Carpenter, Nashville; and Willis C Campbell, Memphis. A symposium on sulfamidamide will be presented by Drs Jefferson C Pennington and Eugene Orr, Nashville; and Gilbert J Levy, Memphis. The Tennessee Academy of Ophthalmology and Otolaryngology will hold its meeting Monday April 11 with Dr Walter L Lillie, Philadelphia, as its guest speaker on 'Neurologic Phases of Ophthalmology'. The Tennessee State Pediatric Society will meet in the morning of April 12 and in a joint session with the medical association in the afternoon.

TEXAS

State Tuberculosis Meeting—The Texas Tuberculosis Association will meet in El Paso April 15-16. Guest speakers will include Drs Jav Arthur Myers, Minneapolis, president of the National Tuberculosis Association, Lewis J Moorman, Oklahoma City, and Mr Holland Hudson, director of rehabilitation of the national association.

Society News—A symposium on carcinoma was presented at a meeting of the Dallas County Medical Society, Dallas, March 10 by Drs Ozro T Woods, who spoke on 'Carcinoma of the Fundus', Charles L Martin, 'Carcinoma of the Cervix', and Harold A O'Brien, 'Genito-Urinary Complications of Cancer of the Uterus'.—At a recent meeting of the Bexar County Medical Society, San Antonio, the speakers, all of the staff of Fort Sam Houston Hospital, were Lieut Col Patrick S Madigan on 'Neuritis', General Polneuritis, Major Harry A Bishop, 'Congenital Heart Disease', and Col Shelby U Marietta, 'Pulmonary Abscess'.—Dr Taylor C Walker, Beaumont, addressed the Hardin-Tyler Counties Medical Society in Kountze in February on 'Differential Diagnosis of

Pain in the Region of the Heart'.—Drs Thomas B B... Fort Worth, and Bam Leake, Gladewater, addressed the Gr... County Medical Society in February on "X Ray Therapy in Pneumonia" and "Syphilis of the Central Nervous System" respectively.—At the February meeting of the Kaufman County Medical Society in Kaufman the speakers were Dr Thomas H Cheavens, Dallas, and William P Philips, Greenville, on "Treatment of Neurosyphilis" and "Lacerations of the Face and Scalp" respectively.

WISCONSIN

New Officers of State Board—Dr William W Kelly, Green Bay, was recently chosen president-elect of the state board of health and Dr John J Seelman, Milwaukee, became president. Dr Joseph Dean, Madison, was elected vice president.

Personal—Dr Francis P Daly, Chippewa Falls, deputy state health officer, was the guest of honor at the annual meeting February 11 of the Old Settlers' Association in Reedsburg where he practiced from 1897 to 1931.—Dr Margaret E Hatfield, Janesville, has been appointed health director of Rock County as part of an enlarged health program made possible by a federal grant of \$5,800. Dr Hatfield has been serving part time in this position.

Society News—Dr Foster L McMillan, Chicago, addressed the La Crosse County Medical Society, recently, on 'Regional Enteritis'.—Dr William S Middleton, Madison, addressed the Outagamie County Medical Society, Appleton, recently, on 'Advances in Treatment of Pneumonia'.—Dr Eben J Carey, Milwaukee, addressed the Rock County Medical Society, Beloit, recently, on 'Role of the Doctor in Health Education of the Public'.—A symposium on "Disorders of the Eye, Ear, Nose and Throat as They Relate to General Practice" was presented before the Medical Society of Milwaukee County, Milwaukee, March 11, by Drs Edward R Ryan, Ferdinand H Haessler, Earl W Martens and Mark J Bach.

GENERAL

President Proclaims April Cancer Control Month—President Roosevelt, pursuant to a joint resolution of Congress, issued a proclamation March 28 designating April as 'Cancer Control Month' and inviting governors of states, territories and possessions of the United States to make similar proclamations. The proclamation invites the medical profession, the press and all agencies and individuals interested in a national program for control of cancer by education and other cooperative means to unite during April in a public dedication to such a program and in a concerted effort to impress the people of the nation with its necessity.

Association on Mental Deficiency—The sixty second annual convention of the American Association on Mental Deficiency will be held in Richmond, Va., April 20-23 with headquarters at the Hotel Jefferson. Among the speakers will be

- Dr Edward J Humphrey, Thell, N Y, 'The Field of Psychiatry in Relation to the Work of State School'
- Drs Henry M Pollock and George Levene, Boston, 'Relation of Pituitary Function to Normal and Abnormal Mental States as Revealed by Roentgenograms of the Skull'
- Dr Clemens E Benda, Wrentham, Mass, 'Studies in the Endocrine Pathology of Mongoloid Deficiency'
- Dr Bronson Crothers, Boston, 'Birth Injuries and the Illnesses of Infancy in the Etiology of Mental Deficiency'
- Dr Arnold L Gesell, New Haven, Conn, 'A Behavior Study of Birth Injury'
- Dr James N Williams, Richmond, 'Emotional Education of Children'
- Dr William B McIlwaine III, Petersburg, Va, 'The Correlation Between the Pediatrician, the Psychiatrist and the Psychologist'

Dr Harry C Storrs, superintendent of Letchworth Village, Thell, N Y, is president of the association and will deliver his official address at a dinner Friday evening April 22.

Physicians and Hospitals Defrauded—A Kansas City physician recently reported a case of fraud perpetrated by a man apparently suffering from angina pectoris, which he said resulted from an alcoholic spree. He asked to be taken to a Catholic hospital, stating that he was heavily insured in the "North American Electrical Engineers," which would take care of all expenses. He said he was an electrical engineer, graduated from Notre Dame University. According to his story, he had received a shock of 30,000 volts of electricity while working in Mexico eight years before. This accident had caused serious cardiac damage which had made him virtually an invalid for three years. Examination revealed a loud diastolic murmur, blood pressure of 150/50 and cardiac (or aortic) enlargement, the physician reported. The excessive pain was relieved

with amyl nitrite and during the time the man was in the hospital he consumed large quantities of pantopon, dilaudid and atropine. He said that he had an aneurysm and had had syphilis. After a week of treatment in the hospital he produced no evidence of money or insurance policies and worked a ruse to escape. A woman who was with him at first was said to have gone to Joplin, Mo., and several telephone calls to Joplin were charged to the hospital. Altogether he incurred obligations of about \$250 and paid nothing. He gave his name as J T Satterlee and was also known as Adams.

First International Health Broadcast May 2—A half hour radio broadcast between England and the United States on rheumatic heart disease will be heard over the National Broadcasting Company Red Network, May 2 at 7 30 p. m., eastern daylight saving time, as an observance of May Day-Child Health Day. The program, said to be the first international broadcast on a health problem, was arranged by the American Heart Association and Irvington House, a convalescent home for children with heart disease at Irvington-on-Hudson, N. Y. Lord Horder, physician-in-ordinary to King George VI, will open the radio conference, speaking from London on public health aspects of the disease. Dr William J Kerr, San Francisco, president of the American Heart Association, will tell of the work of that association in this field. Then from Atlantic City, N. J., Drs Homer F Swift New York, and Thomas Duckett Jones, Boston, will speak on investigations on the cause of the disease and on treatment of children with rheumatic heart disease, respectively. The members of the committee that has arranged this broadcast are Drs Arthur C DeGraff, New York, Edwin P Maynard Jr, Brooklyn, James G Carr, Chicago, Thomas Duckett Jones, Boston, Harold M Marvin, New Haven, Conn., William D Stroud, Philadelphia, Miss Gertrude P Wood, of the American Heart Association, New York, Mrs Edwin H Koehler of Irvington House, and Dr Kerr.

Fiftieth Anniversary of Anatomists—The American Association of Anatomists will celebrate the fiftieth anniversary of its founding at its annual meeting at the University of Pittsburgh April 14-16. The anniversary will be observed with a special program presented by former presidents of the association as follows:

Dr Ross G Harrison New Haven Conn Factors Concerned in Development of the Ear
Dr Robert R Bensley Chicago Plasmosin An Important Constituent of Protoplasm
Dr Clarence M Jackson Minneapolis Nature of Abnormally Rapid Increase in Body Weight Following a Period of Growth Suppression
Dr Florence R Sabin (with Dr Austin L Joyner) New York Tuberculous Allergy Without Infection
Dr George L Streeter Baltimore Origin of the Gut Endoderm in Macaque Embryos
Dr Charles R Stockard New York Structural Disharmony The Genetic and Developmental Independence of the Upper and Lower Jaws

Included on the program of more than 200 papers are the following:

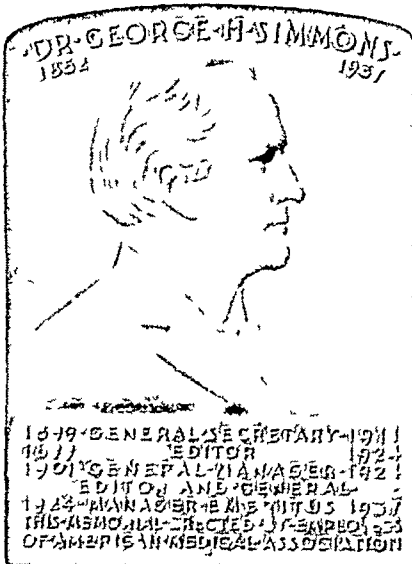

Dr Eben J Carey Milwaukee Experimental Histology of Nerve Fibers
Raymond C Truev MS Minneapolis Changes in the Semilunar Ganglion Referable to Senescence in Man
Dr Patrick Alexis Martin Francis Fitzgerald Waterford Ireland Developmental Problem Presented by the Brain of a Mentally Defective Child
Drs George N Papanicolaou and Emil A Falk New York Production of General Muscular Hypertrophy by the Androgenic Hormone
Carl R Moore PhD Jule K Lamar BS and Naomi Beck AB Chicago Effectiveness of Sex Hormones Administered as Skin Ointment

This meeting will be in conjunction with the annual meeting of the American Association of Physical Anthropologists.

Conference of State and Provincial Health Authorities—The annual Conference of State and Provincial Health Authorities of North America with the U S Public Health Service will be held in Washington, D C, April 9-11. The meeting will open with a symposium on "Recent Extension and the Future of Medical and Public Health Services," with the following speakers: Drs Thomas Parran surgeon general, U S Public Health Service, Ralph C Williams of the Service, Frederick W Jackson, Winnipeg deputy minister of health for Manitoba, and Rosco G Leland, Chicago, director, Bureau of Medical Economics, American Medical Association. Sunday will be devoted to committee work and in the evening there will be a dinner at the Hotel Willard in honor of members with more than twenty-five years service as follows: Drs Cornelius A Harper, Madison Wis., Thomas R Crowder Chicago, Henry E Young, Victoria B C, James A Hayne, Columbia S C, Frederick E Trotter, Honolulu, Hawaii, Arthur T McCormack, Louisville Ky, Charles F Dalton, Burlington, Vt., William F Cogswell, Helena, Mont.,

John A Ferrell, New York, and Theodore B Beatty, Salt Lake City. At Monday's session committees will report and there will be addresses by Drs Earl B McKinley, Washington, on "The Cartography of Disease in the United States" and Bolivar J Lloyd, U S Public Health Service, retired, "The Role of Viscerotomy in the Control of Yellow Fever." Dr Robert H Riley, Baltimore, is president of the conference.

Memorial Tablet to Dr Simmons—Reproduced on this page is a photograph of a bas relief showing the likeness of the late Dr George H Simmons. The tablet is erected by the employees in the headquarters office of the American Medical Association who wished to establish a permanent memorial in honor of Dr Simmons. The bas relief is the work of Mr C Warner Williams, well known sculptor of Chicago, and will hang in the reception room on the first floor of the headquarters building where visitors will have an opportunity to see it. In this reception room there is a bust of Dr Nathan Smith Davis, founder of the American Medical Association, and photographs relating to the historical development of the Association and its work. The

new edition of "Medical Writing" which will shortly be released (Dr Simmons was co-author with Dr Morris Fishbein of the first edition) is dedicated to Dr Simmons and contains a full page reproduction of the bas relief. Dr Simmons, who died Sept 1, 1937, was associated with the American Medical Association as general secretary, editor and then as editor and general manager for twenty-five years.

Government Services

Annual Report of the Surgeon General of the Army

Automobile accidents, the leading cause of death in the U S Army since 1930, again led the list during the calendar year 1936 with 105 deaths, according to the annual report of the surgeon general. This was the highest number in a decade, the previous high being ninety-two in 1931, the number reported in 1935 was sixty-six. Of the total, thirty-eight deaths were attributed to collisions, in twenty-five cases the cause was listed "struck by automobile", in fourteen "car overturned" and in six the car had crashed into objects off the road. There were 1,539 admissions to sick report for automobile injuries. Suicides and airplane accidents occupied the second and third places in the list of causes of death, as they did in 1935, with totals of sixty and fifty-eight, respectively.

The first disease to appear on the list was pneumonia, fourth in the list of causes with thirty-six deaths; this is the first year since 1934 that pneumonia has been first. Cancer and other malignant diseases follow pneumonia with thirty-four deaths; sixth on the list is tuberculosis with thirty-one. Disease of the coronary arteries and angina pectoris, which led the list of diseases for 1935 with forty fatalities, caused twenty-six in 1936.

There were 664 deaths among army personnel in 1936, of which 330 were caused by disease, 334 by injuries. The death rate was 4.03 per thousand compared with 3.84 for 1935.

The leading causes of admission to sick report in 1936 were bronchitis 4,761, influenza 4,490, athletic exercises 4,378, acute tonsillitis 3,829, and gonorrhea 3,726. In 1935 athletic injuries accounted for the largest number (4,046). The total number of admissions for 1936 was 104,379.

During the year there were 1,835,370 days' absence from duty; a daily noneffective rate of 30.5 per thousand of strength. Syphilis and gonorrhea accounted for 14 per cent of the time

lost in 1936, injuries incurred through athletics, automobile accidents and falls for 10 per cent. The average time lost from duty per patient was 17.6 days, compared with 16.6 in the previous year. Gonorrhea was responsible for 196,168 days, athletic exercises were second with 66,509, and tuberculosis third with 61,948. To dementia paralytica was attributed the largest amount of time lost per case (241.3 days). Tuberculosis, which led this list the four previous years, was second with 223.6. Dementia praecox was third with 108.3 and cancer fourth with 108.1.

Influenza was more prevalent than for several years, with an admission rate of 27.3, compared with 19.9 in 1935, pneumonia with 590 cases (an admission rate of 3.6) was also more frequent than in the previous four years. There were 5,919 admissions for venereal disease in 1936, including nineteen cases of venereal lymphogranuloma, the number of admissions in 1935 was 5,010.

The surgeon general reports 1,235 cases of malaria during 1936, of which 532 were in Panama, 486 in the United States and five each in the Philippine Islands, Hawaii and China. There were 413 cases of dengue fever compared with 193 in 1935, 90.8 per cent were in the Philippines. There were four cases of typhoid, all in the Philippines, all these patients recovered.

Among unusual diseases reported for a few cases each were typhus six, lethargic encephalitis four, yaws eleven, undulant fever three, beriberi one, epidemic cerebrospinal meningitis thirty-two, poliomyelitis one, tularaemia three, Rocky Mountain spotted fever two, leishmaniasis one.

The report shows 1,679,492 days of treatment in hospitals and quarters for the regular army, 1,858,744 for other persons including Veterans' Administration, Soldiers' Home, National Guard, Officers' Reserve Corps, Reserve Officers' Training Corps, Citizens' Military Training Camps, Civilian Conservation Corps and other civilians. Outpatients for the year numbered 1,473,190 and the treatments received 2,715,325. There were 521,403 physical examinations and 372,846 vaccinations.

The average daily strength of the army in 1936 was 164,654 an increase of 22,086 over 1935. The average officer strength was 11,723. During the year seventy officers, twenty-three nurses and 2,247 enlisted men were separated from the service on account of disability. The discharge rate for the total army was 14.1 per thousand, as compared with 14.6 in 1935. As for more than ten years (except in 1934), dementia praecox was the leading cause of discharge, there were 248 cases. Tuberculosis, which led in 1934, was second in 1936 with 179 cases, tuberculosis was in third place in 1935. Pes planus was third with 167 for 1936, it was fourth in 1935 as a cause of discharge. Thirty-one officers and 840 enlisted men were invalided home from foreign posts, 813 because of disease and fifty-eight because of injuries. Nervous and mental diseases were the leading causes for invaliding home of patients.

The Army Medical Library celebrated its one hundredth anniversary Nov. 16, 1936. This library now has more than 400,000 volumes with approximately a million items including pamphlets, theses and similar material. During 1936 it added 3,813 bound volumes and 404 unbound volumes. It receives 1,825 periodicals. The second volume of the fourth series of the Index Catalogue, that for the letter B, was completed and issued in May 1937.

At the Army Medical School a new vaccine laboratory was finished in the fall of 1936 and a project on typhoid vaccine has been completed.

Two new registries were added during 1936 to the American Registry of Pathology maintained at the Army Medical Museum: the tumor registry sponsored by the American Society of Clinical Pathology and the dermatologic register sponsored by the American Dermatological Society. Practically all fields are now covered in the registry except neuropathology.

CORRECTION

Sodium Chloride Tolerance in Chronic Nephritis—In the abstracts of papers and discussions presented before the Central Society for Clinical Research in THE JOURNAL March 12, page 841, in Dr. M. Herbert Barker's discussion, the sentence "I believe that the sodium injury is associated with sodium retention" should read "It appears that there are certain cases of renal injury which are associated with sodium retention and intoxication." The last sentence in this discussion should read "When patients in the second half of life are subjected to surgical operation and receive from three to eight liters of salt solution a day or from twenty-seven to seventy-two grams of salt, there is grave danger."

Air Raid Precautions

The government has issued the Householders Handbook on Protection against Air Raids. It is desired to ascertain the views of the local authorities on the book in its present form. Among the contents are simple directions for preparing a refuge room in any type of dwelling, explanations of the purpose and use of a respirator and an outline of precautions against fire. In a preface Sir Samuel Hoare, home secretary, emphasizes the importance of householders cooperating in the defence against air raids. "Every home should have a refuge specially prepared in which the whole household could take cover in greater safety. Begin to collect materials for gas protecting your refuge room, materials for darkening your whole house, the things you need in your refuge room." To prepare a refuge room against entry of gas, any cracks or openings must be sealed up. Window frames must be sealed with gummed strip or pasted paper. To seal a door a piece of wood, padded with felt, should be nailed to the floor, so that when closed the door presses tightly against it. A blanket should be fixed outside the door if the door opens outward, inside the door if it opens inward. If warning is received of the approach of hostile aircraft all windows and doors should be closed, fires in grates extinguished, gas jets turned off and the bath filled with water as a supply in case of fire.

High Voltage Roentgen Therapy of Exophthalmic Goiter

At the Royal Society of Medicine, Drs. E. P. Poulton and W. L. Watt, physician to Guy's Hospital and surgeon in charge of the high voltage roentgen therapy department respectively, demonstrated thirty patients who had suffered from exophthalmic goiter and had been cured or received benefit from high voltage roentgen therapy. The use of x-rays in this disease began soon after their discovery but the technique was defective and the only effect was to burn the skin without producing any change in the gland. Drs. Poulton and Watt began to use the x-rays in 1924 and gradually found that the thyroid would tolerate heavier and heavier doses until finally the present method of high voltage therapy was adopted five years ago. One course of treatment consists of five irradiations to the thyroid: (1) right anterolateral, (2) left anterolateral, (3) right posterolateral, (4) left posterolateral and (5) whole gland direct from the front. The total depth dose is not less than 80 per cent of a skin erythema dose. The procedure depends on the severity of the disease. In young patients for whom time is not an essential factor, the first course of high voltage therapy should be sufficient to effect a cure. To the worker for whom time is important, the full course should be given as soon as possible. It is preferable for the patient to be in bed for a week or ten days during the treatment and to rest as much as possible for one month afterward. Where necessary and the work is light the patient is allowed to continue it even during treatment. In severe cases the first course should be given as soon as possible. Rest in bed for ten or twelve days is essential with a month's complete rest afterward if possible. Results should be assessed in three months. With marked improvement further treatment should be postponed for another three months. With moderate improvement a second full course of treatment should be given. Should the symptoms persist at the end of a year, the question of a third course or other method should be considered. With no improvement a decision must be made between further irradiation and other treatment. In grave cases irradiation must be combined with medical treat-

ment, the primary being spread over three or four weeks, with complete rest for at least two months and further treatment as necessary.

Following Fraser's classification the results were as follows: From 55 to 60 per cent of the patients could do their former work without difficulty (class 1), from 30 to 40 per cent could do their work with difficulty or had to take a lighter job (class 2), from 5 to 10 per cent led an invalid life (class 3). At the demonstration, twenty-one of the patients (70 per cent) were in class 1 and nine (30 per cent) were in class 2. The comment was made that the pulse remained normal during the examination, when a rise might be expected from patients with exophthalmic goiter subject to such an ordeal. In the series auricular fibrillation was uncommon.

Intravenous Drip Method in Treatment of Syphilis

At the March 1 meeting of the Académie de médecine de Paris a paper was read by Dr. Arnault Tzanck in which he stated that the various preparations of arsenic which are the most active antisyphilitic agents cannot always be employed in doses as large as desirable, because of the danger of complications. The latter can be placed in three groups: 1. Late complications such as jaundice and erythrodermias which appear after the treatment has been discontinued; they occur no matter by what route the drug was given. 2. Complications which may be called "mediate," appearing from eight to ten days after administration of arsenical preparations; they are frequently observed after a third injection in the form of an apoplexy. 3. The accidents or complications which appear immediately after an injection. These complications can be avoided by giving neoarsphenamine or similar arsenical preparations by the intravenous drip method at the rate of 0.01 Gm. at the most, per minute. A total of 45 Gm. can be given in three days. This mode of intensive treatment by the intravenous drip method had been previously reported by American syphilologists but Dr. Tzanck stated that he had not seen these reports at the time his own observations were being made. The first dose of 15 Gm. is administered in 150 cc. of physiologic solution of sodium chloride preferably by a vein in the forearm, the injection being given over a period of from three to five hours. A total of 157 patients had been treated by this method up to March 1. The results appear to be better than those observed with any other method. The lesions disappear rapidly. *Spirochaeta pallida* cannot be found either in the lesions or in the lymph nodes the day following the treatment. The Wassermann reaction is negative in two or three weeks. This observation applies especially to cases of persistently positive Wassermann reaction. Complications have not been noted in any of the cases.

Inaugural Lecture of Prof. Rene Leriche

Reference has been made in several recent letters to the candidacy and, later, election of the internationally known surgeon Prof. Rene Leriche as successor of Prof. Charles Nicolle in the chair of experimental medicine at the Collège de France. This is an institution for research in all scientific fields, which although it forms a part of the University of Paris better known as the Sorbonne, is independent of the Faculté de médecine. It is the custom in France for a newly appointed professor to deliver an inaugural lecture in which in addition to a eulogy of the preceding occupant of the particular chair it is customary to treat the question of the lecturer's own view regarding the present and future of the subjects to be covered in the course. After an eloquent eulogy of his predecessor, Prof. Charles Nicolle, the bacteriologist, the immediate objectives of modern surgery were discussed by Professor Leriche.

The first subheading was the endocrine aspect of postoperative complications. The problem of what really transpires after an operation still requires investigation. All our internal mechanism is dominated by endocrine action, hence the patient's emotions prior to a surgical procedure, especially in the case of those who dread it, can be measured by a rise of blood pressure during the initial steps, as the result of increased adrenal activity. It is not only prior to and during an operation but also after it that endocrine factors must be taken into consideration. The second question which requires further study is that of the process of healing of wounds. The role of the various connective tissue elements, ever ready to respond to a call for aid, is a most important one in modern surgery. There is some unknown physiologic impulse which determines that bone defects following operations should be repaired by new bone formation or other action. This is true also of most of the differentiated tissues of fibrous origin. A third field for further research is the mechanisms of pathologic changes. The origin of many diseases still remains a dark chapter despite intensive studies. Every tissue lives its own life, otherwise anarchy would result in the human body. The study of our defensive mechanisms has been almost entirely limited to diseases of bacterial origin. More ought to be known about those due to nonbacterial causes, such as injuries. Changes which are primarily the result of physiologic abnormality are responsible for many lesions. Recent experimental studies have shown that stimulation of the sympathetic, i. e., vasoconstriction, gives rise to leukopenia and that paralysis of the sympathetic, i. e., acute hyperemia to a polynucleosis. If the sympathetic is blocked with procaine hydrochloride in the vicinity of a traumatism an incipient infection can be aborted. The surgical physiology of the sympathetic nervous system offers an endless number of problems for study.

Insurance for Physicians

The National Chamber of Physicians has just created a new insurance organization primarily destined to aid doctors and their families who, as the result of location have not heretofore been able to obtain similar benefits. In some sections of Germany, to be sure, the superannuated practitioner and the surviving relatives of a deceased practitioner have for many years been legally protected against want. The newly organized insurance is governed by the following provisions:

The National Chamber of Physicians and several insurance societies have concluded agreements with respect to the types of insurance (life insurance, disability insurance, old age annuities and so on) which are to be made available to medical men under the new system. In general the benefits obtainable will be: life insurance (cash payment to beneficiary at death of the insured), 2,000 marks, annuity in case of total disability or superannuation, 1,500 marks (a retirement annuity begins when a man has reached the age of 64), annuity to insured's widow, 1,000 marks, annuity to child (mother living), 300 marks, annuity to completely orphaned child 600 marks. Each child who is a direct beneficiary of the foregoing insurance will receive an annuity until he reaches the age of 21.

A special board has been appointed to administer the new insurance. Doctors registered with the various local medical boards will be expected to take out the new type of insurance, exempted from compulsory contributions; however, are doctors older than 40½ years, assistants, men who serve constantly as locum tenentes, medical officials and employed doctors who already have a legitimate claim to retirement pensions and survivor benefits. Likewise exempted are doctors who already carry a commensurate amount of life insurance and married women doctors whose husbands carry similar insurance.

Doctors who are legally exempt are permitted to participate voluntarily in the new insurance

The amount of the premiums will be based on percentages of a practitioner's professional income, the exact scale has yet to be computed. If a doctor is over 40½ years of age, the medical professional organization makes to the insurance company a single extra payment of the amount necessary to bring the entrance age of the insured doctor down to 40½ years, the doctor then makes an extra payment to the medical organization, either in a lump sum or in instalments

Studies of Splenic Function

Several aspects of the function of the spleen were recently discussed by Dr. Erwin Schliephake at the Berlin Medical Society. The influence of the spleen on the sympathetic nervous system can be better understood through studies of the interrelation of the spleen and the thyroid. The thyroid secretion reduces vagal irritability. Thyroidectomy is followed by greatly increased vagal irritability and a decreased irritability of the sympathicus. The author has found that, after splenectomy, phenomena produced by thyroidectomy may be in part reversed, thus is demonstrated a splenic influence on the parasympathetic system analogous to the influence exerted by the thyroid on the sympathicus. Verification of these observations was obtained by injections of splenic extract. There was an increase in sensitivity to toxins which stimulate the vagus. From studies of splenic influence on gastric function, contradictory data were at first elicited. Only after examination of a large material was any regularity of reaction discernible, superacidity depreciated the acid values, whereas subacidity increased them. Normal acid values were on the contrary scarcely influenced. It thus became possible to determine the regulatory function. In healthy subjects who received injections of splenic extract the blood sugar values were lowered, but not in equal measure, several hours after the initial decline there appeared a temporary increase, which was succeeded by a second decline, only first after from eight to ten hours had elapsed were the initial values restored. The water content of the blood was observed to undergo a similar sequence of phases, administration of splenic extract was immediately followed by a depreciation of the value (as measured by the refractometer), followed by a rise and finally a second decline. (The splenic extract used contained no protein.) According to Schliephake, the importance of the spleen in prevention of disease is attested by various phenomena: increased phagocytosis following administration of splenic extract, an impetus to the formation of antitoxin, and an increase in the cholesterol value of the blood.

The Specialist's Diploma

The Académie royale de médecine has addressed to the minister of health the following memorial:

The Académie is thoroughly conversant with the various objections raised by certain elements of the profession to the proposed creation of a specialist's diploma. These objections have not been cogent enough to modify the stand taken by the Académie. Each of the stock objections is herewith cited and refuted, they are essentially of two kinds: objections of a juridical nature and objections that concern the *modus operandi*.

I JURIDICAL OBJECTIONS

Many doctors fear that the establishment of a specialist's diploma would divide the profession, in the eyes of the laity, into two classes: "superior" doctors and "inferior" doctors. But present-day lay opinion already envisages a certain hierarchy among the medical profession, prominent specialists and doctors clothed with official functions (university professors,

heads of hospital services, and so on) are popularly considered of a higher order than the rank and file of general practitioner. Therefore the specialist's diploma would after all represent merely an official acknowledgment of an already existing status quo. This legal recognition of the peculiar training required by the specializing physician would redound to his prestige and protect him against unethical competition of improperly trained, self-styled "specialists." The fear has been expressed that under the proposed regulation a practitioner who lacks the specialist's diploma might be accused of having transgressed the limits of his competence and at the same time be held responsible for some alleged injury to the patient. However, it is stated in the preamble to the bill sponsored by the Académie that the new regulation in no way restricts the activities and privileges conferred by the degree of doctor of medicine, surgery, and obstetrics. The holder of this degree will retain the right to perform any ethical medical act. A patient therefore will be permitted no more grounds for action against a practitioner than he possesses under the present laws, which recognize allegations of gross ignorance, negligence or misconduct. The chief purpose of the proposed specialist's diploma is to enlighten the public.

II OBJECTIONS WITH REGARD TO *MODUS OPERANDI*

Quite as vociferous as the objections on juridical grounds have been the exceptions taken to the principle of compulsory examination envisaged in the proposed regulation.

1 Principle of compulsory examination. Certain parties are pleased to claim that the final examination for the doctor's degree in medicine, surgery and obstetrics represents the ultimate official and legal certification of a practitioner's competence. Persons who reason thus should recollect that the man who acquires a special scientific title such as "special physician" or "agregé in higher education" has to undergo tests which in many respects have the character of a formal examination. Similarly, a doctor who seeks membership in one of those scientific societies which represent the elite of the medical profession is usually required to prove himself worthy of admission by submission of an original thesis to be passed on by a committee. Even now there are certain specialist's diplomas which attest that the holders have passed a special examination. Why should not a like certification be required of the practitioner who claims to possess a particular skill in this or that medical discipline? The Académie feels that the granting of these certificates ought properly to be placed under the authority of the university medical faculties. These scholastic bodies would be empowered to determine the amount of study requisite in each specialty, to evaluate the extracurricular training, to hold the examinations of candidates and to appoint the personnel of the examining boards.

2 Alleged antidemocratic character of the proposed regulation. The point has been repeatedly made in speeches and articles that, since special medical training is as a rule available only in the larger hospitals, both university and nonuniversity of the big cities, the proposed specialist's diploma would only be accessible to doctors established in the larger centers or provided with ample financial resources. The Académie concedes the justice of this last objection but believes this inequality of opportunity can be easily obviated. It should be legally stipulated that candidates who desire to be examined in their special disciplines but who have not taken the prescribed course of study may, after a certain number of years of actual specialized practice, submit themselves to examination and on passing receive the specialist's diploma. The Académie does not see the slightest curtailment of rights at present conferred by the degree of doctor in medicine, surgery and obstetrics, nor does it seek to deter the holder of this degree from the performance of any medical procedure whatever. The salient feature of the proposed regulation is that several years of specialized practice would be required of all candidates for the specialist's diploma.

This document will be in essence a brevet of mastery and will carry with it no other privilege than the right to use the title. To clarify its aims, the Académie makes public a condensed restatement of the resolutions passed by it in 1933. Resolved (1) that the public authorities forbid the use of the title "specialist" by any physician not a holder of the special diploma which confers the right to this title and (2) that so far as possible the direction of the special services of those public health services whose members or clients do not enjoy free choice of physician should be reserved to the holders of the new diploma.

National Alimentation Committee

A Comité national de l'alimentation has just been created. The problem of nutrition has come to assume a new importance in Belgium from the standpoint of public health and from that of national economy. The minister of public health decided that concerted investigations of this problem were necessary. The new committee will have as its principal task the formulation of a national food policy. The committee will collaborate with all interested organizations, national and international, and with the League of Nations. It will appoint both members and nonmembers to serve on four subcommittees, the special duties of which will concern, respectively, (1) biologic studies, (2) social and statistical studies, (3) problems relative to the control of foodstuffs, and (4) education, propaganda and methods in the domain of a national food administration.

Occupational Training of Crippled Persons

The minister of labor and social providence has just established an investigatory commission that is to reexamine the whole problem of occupational training for the crippled and the maimed. The commission will investigate the social destiny of persons who receive benefits from the Foundation for Crippled and Maimed Persons and persons who have not been aided by this organization. This means a comprehensive study of the problem. In particular, efforts will be made to enumerate all cases of crippling and maiming and to note whether treatment has been too hastily or too tardily initiated. Furthermore all special vocational training schools and similar establishments will be inspected and plans for the expansion of the existing facilities and the foundation of new institutions will be studied.

Congress of Dwarfs in Budapest

Just as it is widely known that the center of the watch trade is Geneva, the center of the steel industry is Sheffield and the center of the fur market is Leipzig, it is just as well known that the center of Europe's dwarf market is in Budapest. All the shows of Europe and even many overseas varieties visit the Budapest market if they want dwarf artists. The dwarfs of Europe resolved to hold a congress in Budapest to which they intend to invite all the dwarfs of the world and here they plan to discuss the ways and means by which they can combat the general conception that dwarfs are good only for exhibition and that they are not suited to regular civilian occupations. They want to show the world that they are capable of filling all kinds of industrial and even intellectual posts. The date of the congress has not yet been set.

The Sports of the Sick Man

Dr Daniel Kellner, a notable sports physician said at a recent meeting of the medical society that gymnastics is the nature given remedy for effeminacy. No every efficacious remedy has a dose which within certain limits varies according to the individual thus also sports must be dosed even if one is dealing with perfectly healthy men and all the more so with

not wholly healthy persons, for whom modern physicians not only do not forbid participation in sports but even suggest a moderate degree of athletics. These patients perhaps need the physiologic stimuli hidden in motion rather more than vigorous and strong athletes do. Over the physical exercises of persons suffering from chronic diseases constant medical control must be applied, because only thus can physical exercises become useful and not harmful to the patient. In young persons of the asthenic type, who according to our knowledge are less resistant, physical exercise, commenced cautiously and continued with gradual increase, is the only way toward improvement. Patients suffering from valvular diseases may require moving. Terrain therapy on sloping places were known of old and were applied by physicians prior to the "sports craze." Of course in these cases medical control is implicitly necessary, because in the same subject, according to the different stages of the disease, rest is at one time required and then movement of a certain extent. In instances of compensated and balanced valvular disturbances, likewise in cases of moderate hypertension, light gymnastic exercises, outdoor games, exercises of the abdominal muscles and hunting may have a good effect. But racing or climbing means a greater effort and is conducive to high blood pressure. In metabolic disorders, such as diabetes, obesity or gout, physical exercises in gradually rising increments may prove beneficial. To get rid of excessive deposits of fat on the abdominal wall, rowing, walking, moderate running and gymnastics of the abdominal muscles are to be recommended. Of course, in addition, adequate diet and certain drugs cannot be dispensed with. In diabetes and gout moderate exercise, hunting, riding, tennis playing and rowing are recommended by prominent clinicians. For women suffering from disturbances caused by the climacteric, sports and outdoor pastimes are much to be recommended, their action being invigorating also on their minds, refreshing bodily movements have a favorable influence on the labilities of mood connected with the change.

AUSTRALIA

(From Our Regular Correspondent)

March 2, 1938

The State and the Medical Profession in Queensland

The future of medical practice in Queensland is at the crossroads. The commonwealth government is seriously bent on national insurance with the support, in principle, of the Federal Council of the British Medical Association. The Queensland government, on the other hand, tends toward a hospitalization program. The Queensland branch of the British Medical Association has been endeavoring to counter its government's tendency by urging a scheme of its own which is based on the "lodge" system, using the existing friendly societies as an administrative basis. Into this sea of conflicting ideas was launched through the daily press, January 12, an "open letter" to medical men from the director general of health and medical services purporting to be a request for cooperation with the Queensland government. Shortly after its appearance in the press, a questionnaire was sent to all practitioners in Queensland. They were asked to signify whether they were willing, if called on, to enroll with the department of health, for various types of hospital insurance or preventive medical work, on a full time or a part time basis. In view of the fact that the Queensland branch of the British Medical Association has been complaining for several years that it was unable to make contact with the department of health, much less cooperate with it, the present appeal from the director general was greeted with surprise.

In September 1935 the Queensland branch of the British Medical Association published a scheme for a national medical service for the state. It was based on the provision of a general practitioner for every family. The association proposed that

the scheme would be financed by compulsory medical insurance, with government subsidy to provide for the unemployed and for chronic invalids. The association was opposed to full time nationalization on the ground that it would be detrimental to the profession and the patient. It was emphatic that the patient's right of free choice of a doctor should be preserved. The minister for health stated at the time that the scheme was vague, that it had not been supported by actuarial evidence and that the government would not commit itself without obtaining the fullest information. In February 1936 the British Medical Association asked for the establishment of a joint committee to examine, from a professional and actuarial standpoint, the policy for a general medical service. The minister's reply to this was that the association should formulate a definite scheme showing exactly what contributions would be required from the public and what benefits contributories would receive. For two years no further progress was made. Now the appeal comes from the department to the medical profession not from the minister but direct from his professional adviser, and not through the medium of the British Medical Association but by means of the press, and by circulars to individual practitioners.

The appeal for cooperation is taken to mean that the government proposes shortly to extend its activities to the provision of public medical services. Possible inferences from the letter are (1) that the government would retain a limited number of doctors who would be wholly paid from public funds or (2) that a large number of doctors would be paid to devote part of their time to public medical service. It is not known to what extent any such scheme would be affected by the federal national insurance plans, which presumably would bear part of the cost of such a scheme. Probably by the time the commonwealth proposals can be put into effect the Queensland scheme would be well developed. The open letter indicated the increased demand by the poorer sections of the community for medical care and for which, under the existing system, they are incapable of paying.

It was pointed out by the *Medical Journal of Australia* that Sir Raphael Cilento, the Queensland director general of health, had taken practically the whole of his letter from papers read at the Philadelphia conference February 1934 on the subject "The Medical Profession and the Public Currents and Counter Currents." These speeches were made by men opposed to the American Medical Association because it was not prepared to approve a scheme of national insurance for the United States. The Queensland branch council of the British Medical Association advised members of the branch that they might reply in the affirmative to all the questions in the circular letter, with the proviso that acceptance is subject to the qualification that the conditions of service are satisfactory and are approved by the Queensland branch of the British Medical Association. The waters are as troubled as ever because in spite of its high sounding phrases it did not commit the government to any future in particular. A frank round table discussion would have been a much easier method of exploring the possibilities which the future holds forth.

Fee Splitting Illegal in Victoria

A bill prohibiting composite accounts and the sharing of fees has been passed in the legislative assembly of Victoria. It is now illegal for a medical practitioner to present an inclusive account for services rendered by himself and other doctors. This practice has been the cause of complaints from the public, and the Medical Board of Victoria requested that suitable action should be taken to put an end to a method of account rendering which is open to abuse. A patient who pays an account covering the services of more than one doctor is unaware of the fees payable to the other doctor or doctors, who in turn are unaware of the fees included on their behalf, in the composite account. This is considered unfair to the patient and contrary to the best

interests of the medical profession. The bill remedies the situation by prohibiting a medical practitioner from demanding payment, presenting an account or collecting fees for professional services rendered by any other medical practitioner, except a partner, assistant in his sole employment or locum tenens, and forbids a medical practitioner to share, or agree to share, fees for professional services with any doctor other than a partner, assistant or locum tenens. Partnership agreements must be approved and registered by the medical board, to prevent the defense being raised that doctors are carrying on their profession in partnership. Sir Stanley Argyle, speaker in the assembly, supported the bill, stating that it was designed chiefly in the interests of the public to prevent its exploitation between general practitioners and specialists or between general practitioners and surgeons or consultants. At a special meeting of the Victorian Branch of the British Medical Association the opinion was expressed that the bill was unnecessary and that its effect would probably be to prejudice confidence between doctor and patient. Regret was expressed that the branch had not been given an opportunity to consider the details of the bill before it was passed. Subsequently however the meeting approved of the bill, and that approval was conveyed to the government.

Legislation for Control of Biologic Products

The commonwealth government, in the Therapeutic Substances Act of 1937, has introduced a measure of control over the preparation, import and export of biologic products. The legislation is to apply only to therapeutic serums, bacterial products and glandular extracts. No control is exercised over such more strictly chemical substances as the arsphenamines, digitalis and strophanthus. For the purpose of this act a therapeutic substance is defined as one which is "wholly or in part derived from microscopic organisms or from living cellular tissues or from glands removed from animals after slaughter." This legislation followed the conference on biologic standardization held at Geneva in October 1935, in which Australia was represented among twenty-four countries. It now standardizes the definitions of therapeutic units throughout Australia. Previously, three states had adopted the standard of the Hygienic Laboratory at Washington, while the remaining two Australian states had not accepted any standard. There is only one Australian source of therapeutic serums, the commonwealth serum laboratories. Serums of other sources are imported but they have to contend with a high tariff wall. The commonwealth laboratories have served well the demands of such products in Australia and New Zealand.

Marriages

FREDERICK WILHELM VAN BUSKIRK, Jr., Pottstown Pa. to Miss Margaret Moffitt of Asheville N. C., in Greensboro, N. C., Dec 29, 1937

RUSSELL MACRAE ATCHISON, Northville, Mich., to Miss Ruth Mary Baldwin of Jonesville, in Albion January 22

LEIGH G. COLLINS, West Point, Neb., to Miss De Lene Helrick at Lincoln, recently

EDWARD ARNOLD, Canton, Ohio to Miss Melba Leav of Demopolis, January 27

THOMAS E. WARD to Miss Evelyn Bartlett, both of Williamsport, Ind., January 19

ABE C. FELLMAN to Miss Betty Fellman, both of Omaha, February 27

MORTIMER M. KOPF to Miss Lillian Lux, both of Brooklyn March 11

HERBERT D. KLEPER, Kenesaw, Neb., to Miss Marie Bay in January

Deaths

George Henry Crabtree * Colonel, U S Army, retired, Sedro Woolley, Wash, Medico Chirurgical College of Philadelphia, 1893, veteran of the Spanish-American and World wars, entered the army as an assistant surgeon in 1901, rose through the various ranks, retired Jan 29, 1917, as a lieutenant colonel, returned to active duty April 24 1917, and served until 1919 retired as a colonel June 21 1930 on the staff of the Northern State Hospital and State Narcotic Farm Colony, aged 67 died, January 16, in the Rowley Hospital, Mount Vernon

Edwin Benjamin Ramsdell, White Plains, N Y University of the City of New York Medical Department, 1878, member of the Medical Society of the State of New York, examining surgeon for pensions, department of interior, 1890-1894, assistant surgeon to the Manhattan Eye and Ear Hospital, 1881-1891, attending surgeon to the New York Nose and Throat Hospital, 1891-1900, medical officer to the New York fire department, 1895-1920, aged 81, died, January 19, of chronic myocarditis

Grayson Emery Tarkington, Albuquerque, N M, University of Maryland School of Medicine, Baltimore, 1917, member of the New Mexico Medical Society fellow of the American College of Physicians, served during the World War, on the staffs of the Children's Home and Hospital, Southwestern Presbyterian Hospital and St Joseph Sanatorium and Hospital, aged 43, died, January 12, as the result of injury received in a fall

James M Smith * Valdosta, Ga, Atlanta Medical College, 1898 member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, past president of the Medical Association of Georgia on the staff of the Little-Griffin Private Hospital aged 62 died, January 8 of a malignant condition of the intestinal tract

Arthur Brown Bisbee, Montpelier, Vt, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1882, member of the Vermont State Medical Society on the staff of the Heaton Hospital for many years medical director of the National Life Insurance Company, aged 79, died, January 31, of arteriosclerosis

Marshall Ashby Purse, St Simons Island, Ga, Southern Medical College, Atlanta, 1890 College of Physicians and Surgeons, Medical Department of Columbia College New York, 1892, member of the Medical Association of Georgia, aged 71, died, January 7 at a hospital in Brunswick of coronary thrombosis and myocarditis

George Fisk, Montreal, Que, Canada, University of Bishop College Faculty of Medicine, Montreal, 1894 fellow of the American College of Surgeons, served during the World War, consulting surgeon to the Woman's General Hospital, aged 69, died January 28

Frederick John Fox, New York, University of Toronto Faculty of Medicine, 1908 formerly senior attending dermatologist to the West Side Hospital and Dispensary aged 59, died, January 6, in the British Guiana jungle, while with a party searching for Paul Redfern long missing American aviator

P Calvin Hartford * East Palestine, Ohio, Western Reserve University Medical Department, Cleveland, 1887, Jefferson Medical College of Philadelphia 1894 past president of the Columbiana County Medical Society on the staff of the Salem City (Ohio) Hospital, aged 75, died January 3

George F Warmburg, Milwaukee Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin Prussia, Germany, 1891 member of the Washington State Medical Association aged 72 died, January 19, in the Columbia Hospital, of cerebral infarction and hypostatic pneumonia

Louis Miller, New York Columbia University College of Physicians and Surgeons, New York 1907 formerly adjunct professor of internal medicine at the New York Polyclinic Medical School and Hospital aged 55, died, January 1, in Miami, Fla of acute coronary thrombosis

Robert Augustus Hamrick, Clay, W Va (licensed in West Virginia in 1903), county health officer and county coroner, chairman of the medical draft board in Clay County during the World War at one time mayor of Clay, aged 68 died January 27, of coronary thrombosis

Daniel Waldo Fenton * Reading Mich Detroit Medical College, 1876, formerly secretary of the Hillsdale County Medical Society at various times mayor, member of the council and secretary of the board of education aged 89, died January 8, of coronary thrombosis

Charles Louis Rudasill * Richmond, Va, Medical College of Virginia, Richmond, 1914, medical director of the Life Insurance Company of Virginia, served during the World War, aged 47, died, January 13, in the Tucker Sanatorium, of a self-inflicted bullet wound

Alfred Michaelis * New York, Columbia University College of Physicians and Surgeons, New York, 1898, assistant professor of otolaryngology at his alma mater, aged 63, on the staff of the Presbyterian Hospital, where he died, January 27, of angina pectoris

E Jones Stroud, Chicago, Loyola University School of Medicine, Chicago, 1929, member of the Illinois State Medical Society, on the staff of the Little Company of Mary Hospital, Evergreen Park, Ill, aged 45, died, January 11, of lobar pneumonia

Eilef A Smedal * La Crosse, Wis, Rush Medical College, Chicago, 1916 past president of the La Crosse County Medical Society, aged 48, on the staff of St Francis Hospital, where he died, January 30, of pulmonary tuberculosis and diabetes mellitus

George Homer Buffington, Decatur, Ark, Keokuk (Ia) Medical College, College of Physicians and Surgeons, 1900, member of the Arkansas Medical Society, formerly mayor of Gravette, bank president, aged 68, died, January 24, of heart disease

Thomas Obadiah Senior, Nashville, Tenn Meharry Medical College, Nashville, 1923, professor of dermatology at his alma mater aged 54, on the staff of the Hubbard Hospital, where he died, January 8, of chronic appendicitis and cholecystitis

De Witt Clinton Jones, St Paul, Trinity Medical College, Toronto, Ont, Canada, 1891, Victoria University Medical Department, Coburg, Ont 1891 formerly county coroner, member of the Minnesota State Medical Association, aged 69, died, Dec 23, 1937, of coronary occlusion and sclerosis

William Fennelly McGrath, North Adams, Mass, Baltimore Medical College, 1894, at one time city physician, on the courtesy staff of the North Adams Hospital, aged 72, died suddenly, January 24, of chronic myocarditis and nephritis

Malcolm Morris Restall * Marblehead, Mass Harvard University Medical School, Boston, 1926, on the staffs of the Salem (Mass) Hospital and the Mary Alley Emergency Hospital aged 39, died January 25, of coronary occlusion

Marion Masters Ricketts * Sadorus, Ill, Chicago College of Medicine and Surgery, 1911, on the staffs of the Burnham City Hospital, Champaign, and the Mercy Hospital, Urbana, aged 60 died, January 14, of pulmonary tuberculosis

Robert E Chumbley, Radford, Va, University College of Medicine, Richmond, 1898 member of the Medical Society of Virginia, aged 64, died, Dec 31 1937, in the Jefferson Hospital, Roanoke of perforated duodenal ulcer

Eugene McEvers Van Ness, Baltimore University of Maryland School of Medicine, Baltimore, 1891, member of the Medical and Chirurgical Faculty of Maryland, aged 69, died, January 12, of carcinoma of the pancreas

Crandall A Reynolds, Lincoln Neb Nebraska College of Medicine, Lincoln, 1908 member of the Nebraska State Medical Association, on the staff of St Elizabeth's Hospital, aged 57, died, January 16, of angina pectoris

George Carr Taylor, Mentone Ind, Chicago College of Medicine and Surgery, 1910, member of the Indiana State Medical Association served during the World War, aged 57, died, January 23, of cerebral hemorrhage

Joseph Eugene Turcot, St Hyacinthe Que, Canada, M B, Laval University Faculty of Medicine, Quebec, 1873, and M D in 1875 formerly on the staff of St Charles Hospital, aged 87, died, Dec 11, 1937

Jessie Penrose Smith, Pennsville Ohio Ohio Medical University Columbus 1896, aged 72 died January 27, in the Memorial Hospital, Marietta, of burns received when her clothing ignited from a gas grate

Andrew J Marberry, San Angelo, Texas, Missouri Medical College, St Louis, 1881 member of the State Medical Association of Texas, aged 84, died, January 2, of arteriosclerosis and heart disease

Luther A Barnes, Huntsville, Texas, Memphis (Tenn) Hospital Medical College, 1907 member of the State Medical Association of Texas aged 56, died January 27, in Apopka, Fla, of angina pectoris

Edward Tuck Manix * Lynn, Mass, Harvard University Medical School, Boston, 1898 formerly on the staff of the Lynn Hospital aged 61 died, January 19, of arteriosclerosis and coronary thrombosis

Hugh Ralph Martin, Riverside, Calif., Creighton University School of Medicine, Omaha, 1937, intern at the University of Kansas Hospitals, Kansas City, aged 26, died, January 30, of pneumonia

Henry T Dixon, Evansville, Ind., University of Louisville (Ky.) Medical Department, 1879, formerly secretary of the city board of health, aged 87, died, January 13, of cerebral hemorrhage

Louis Jalmer Smith, Chester, Ill., St. Louis University School of Medicine, 1903, formerly physician to the Southern Illinois Penitentiary, aged 66, died, Dec 1, 1937, of arteriosclerosis

Ezra Herbert Perry, Providence, R. I., Bellevue Hospital Medical College, New York, 1870, aged 89, died, January 3, of bronchopneumonia, diabetes mellitus and arteriosclerosis

Otis Burgess Moye, Soperton, Ga., Atlanta College of Physicians and Surgeons, 1900, aged 62, died, January 23, in Lake Wales, Fla., of chronic myocarditis and hypertension

Joseph M Murray, Hollandale Miss., University of the South Medical Department Sewanee, Tenn., 1901, aged 67, died, January 23, of carcinoma of the tongue and throat

Andrew McAlpine McCune, Rose Hill, Miss., Memphis (Tenn.) Hospital Medical College, 1899, aged 65, died, January 12, of chronic nephritis and rheumatic heart disease

William Thomas Thompson, Texarkana, Texas, Meharry Medical College, Nashville, Tenn., 1914, aged 53, died, January 26, of cerebral hemorrhage and hypertension

Jedd D Walker, Hogansville, Ga., Southern Medical College, Atlanta, 1886, died, January 7, in the Newnan (Ga.) Hospital, as the result of injuries received in a fall

Sidney Fain Hutcherson, Adairsville, Ga., University of Georgia Medical Department, Augusta 1913, aged 51, died suddenly, January 12, of coronary occlusion

Thomas Rowe Price, Glyndon, Md., University of Maryland School of Medicine, Baltimore, 1891, aged 72, died, January 16, of carcinoma of the prostate

Herbert Crawford Perkins, Boston (licensed in Massachusetts in 1899), aged 61, was found dead in his automobile, January 29, of cerebral hemorrhage

Felix Manning Brown, Hopkinsville, Ky., Vanderbilt University School of Medicine, Nashville, Tenn., 1893, aged 66, died, January 25, of arteriosclerosis

Lewis Farwell Voke, Columbus, Ohio, Starling Medical College, Columbus, 1896, aged 70, died, January 9, in Clermont, Fla., of chronic myocarditis

W Guy Beals, Lake Valley, N. M., Hahnemann Medical College and Hospital, Chicago, 1883, aged 84, died, Dec 24, 1937, of cerebral hemorrhage

Malcolm A McEachern, Northcarrollton Miss., Memphis (Tenn.) Hospital Medical College, 1900, aged 65, died, January 10, of lobar pneumonia

M C L Kirksey, Dardanelle, Ark., Memphis (Tenn.) Hospital Medical College, 1897, aged 68, died, January 16, of hypertensive heart disease

Charles Forest Henderson, Los Angeles, St. Louis University School of Medicine, 1905, aged 58, died, January 24, of coronary thrombosis

Carl August Vogel, Cincinnati, University of Cincinnati College of Medicine, 1932, aged 30, died, January 28, of a self-inflicted bullet wound

Leo Rubin, Los Angeles, Long Island College Hospital Brooklyn, 1913, aged 49, was found dead, January 10, of coronary thrombosis

Alfred Seeley Wade, Renfrew Ont., Canada McGill University Faculty of Medicine, Montreal, Que., 1892, aged 67, died, January 8

James Hawkins Heflin, Atlanta, Ga., Atlanta Medical College, 1895, aged 63, died, January 24, of carcinoma of the esophagus

Robert H Steinbach, Battle Creek, Mich., Detroit College of Medicine, 1896, aged 64, died, January 17, of cerebral hemorrhage

Clifford Lansing Terrill, San Francisco, Hospital College of Medicine, Louisville, Ky., 1903, aged 58, died Dec 5, 1937

Benjamin J Kent, Oil Trough, Ark. (licensed in Arkansas in 1903), aged 61, died, January 3, of cirrhosis of the liver

John A Henry, Hope, Ark., Louisville (Ky.) Medical College, 1890, aged 76, died, January 30, of chronic nephritis

John W Fleming Sr, Saltpa Ala., Medical College of Alabama, Mobile, 1879, aged 88, died, Dec 12, 1937

Bureau of Investigation

THE GERALD'S BALM FRAUD

A Rupture Cure Swindle Debarred from the Mails

Under the trade styles "Gerald's Balm, Inc.," "Cooperative Balm Company" and "Cooperative Laboratories," all of Baltimore, there has been sold a fraudulent "patent medicine" called variously "Miracle Rupture Balm" and "Gerald's Balm." The stuff, which was sold through the mails, was an ointment consisting chiefly of petrolatum (90 per cent) and small amounts of red pepper, oil of mustard, turpentine and oil of wintergreen. The claims were made that by rubbing this mixture over a rupture visible results might be expected in three days, that trusses could be dispensed with and that persons who had suffered from hernia "for over 40 years" would be cured!

As is usual in "patent medicine" exploitation, the men behind this fraud were quite without any medical knowledge and the business had no physicians, pharmacists or chemists connected with it. In fact the concern was operated by two men: (1) Samuel Cohen, who had been in the clothing business and had never had even a high-school education and (2) Murray Emanuel who had previously been employed by a finance concern. Cohen manufactured the nostrum himself.

In May 1937 the office of the Solicitor for the Post Office Department called on the concern to show cause why a fraud order should not be issued in the case. On June 2, Cohen and his attorney appeared in Washington and the evidence in the case was heard. According to the government report on the case the rupture cure concern produced a witness in the person of Dr. J. Page Strong of Baltimore. The biographic records of the American Medical Association show that James Page Strong was graduated in 1907 when he was 37 years old by the Maryland Medical College and was licensed in Maryland in 1908. Dr. Strong is not a member of his local medical society nor, of course, of the American Medical Association. The doctor is reported, was unable to explain just how a mixture of petrolatum, red pepper, turpentine and mustard would reach the hernial cavity or penetrate through the several overlying tissues to the seat of the rupture.

Dr. Strong is said to have admitted that Gerald's Balm was a rubefacient or counter-irritant but he also insisted that when it reached the hernial opening it acted as an astringent. While agreeing that a counter-irritant and an astringent acted directly contrary to each other he was apparently unable to explain how the preparation had one effect on the skin and a directly contrary effect when it—allegedly—reached the hernia. Further, the doctor is said to have admitted that no one of the ingredients in the nostrum would reach the hernia in and of itself but to have claimed that the combination of the drugs in the "patent medicine" would do so. Yet Dr. Strong did not even know the ingredients of the stuff until he heard them at the meeting! The doctor, according to the government report, stated that he was not a surgeon, did not specialize in the treatment of hernia and, continues the report, "in fact showed by his testimony that he was somewhat unfamiliar with the anatomy of the human body at that point."

Physicians who testified for the government brought out the facts that there is no drug or combination of drugs known that, when applied externally, will cure hernia, that the preparation would not produce gratifying results in persons suffering from ruptures as large or larger than that of a chicken egg or of any other size as claimed that it would not produce visible results in three days that the representation that ruptured persons using the balm could dispense with their trusses was dangerous to health and life and that there was absolutely no possibility of a cure from rupture existing for over 40 years by the use of the preparation.

The Solicitor for the Post Office Department Judge Karl A. Crowley declared that the evidence in the case showed that this was a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises and he recommended that the Postmaster General issue a fraud order. On June 7, 1937 the order was issued.

Correspondence

THE THERAPY OF JAUNDICE—AN ADDITION

To the Editor—In the article on jaundice (THE JOURNAL, March 5) under section F, Icterus of the New-Born, No 2, the grave form of icterus, erythroblastosis is not mentioned. A percentage of recoveries in this disease may be secured by transfusion. In these cases other causes of icterus neonatorum should be ruled out, and if this is done a percentage of cases is left that it is impossible to account for except on some other theory. Such a theory is that of erythroblastosis which occurs in two types, the hydrops and the icteric. In the latter, the jaundice comes on early and is severe, but if transfusion is done early and repeated as needed a percentage of recoveries may be assured.

ALBERT E. STEELE, M.D., Boston

DANGERS OF BURNING FROM CELLOPHANE COSTUMES

To the Editor—The Dennison Manufacturing Company sells for 10 cents a book entitled "How to Make Gay Colorful Costumes of Crepe Paper." Costume 9 on page 9, is described under the title 'cellophane' and the book states "You will feel very glamorous indeed in a Cellophane costume. Better not smoke while you are wearing it."

I labored under a charge of being dogmatic when I emphatically refused to allow my daughter to have such a costume for a party. I argued that, any time three people over 16 years of age get together, at least one is smoking. To make a cellophane party costume is to go a long way out of the way in the search for trouble. A costume was provided of less inflammable material and the incident was forgotten. It comes to mind again today, on receipt of a letter from a relative who writes of a 5 year old girl 'who went to a Halloween party. The children were given Chinese lanterns with candles and the little girl's cellophane costume caught on fire and she died the next morning'.

How much interest can be aroused on the part of so called home magazines to warn of the fire hazard of a product that advertises in their pages remains to be seen. Physicians charged with the responsibility of the health and life of their patients will do well to call their patients' attention to this fire hazard and urge that the patients pass along the warning by word of mouth. The prevalence of smoking by persons of both sexes and almost all ages makes inflammable party costumes strictly contraindicated.

RAMSAY SPILLMAN, M.D., New York

THE DUBLIN TREATMENT OF ABRUPTIO PLACENTAE

To the Editor—In a recent paper on premature separation of the placenta, Frederick C. Irving (*Am J Obst & Gynec* 34:881 [Nov.] 1937) concluded that conservative treatment offers the best prognosis for the mother. He follows the suggestion of J. O. Polak (*ibid* 21:218 [Feb.] 1931), using the so called Dublin treatment: rupture of the membranes, tight cervical and vaginal pack, and Spanish windlass. This method was introduced at the Rotunda Maternity Hospital in Dublin many years ago. Tweedy strongly advocated this treatment in 1909. R. J. Heffernan (*New England J Med* 214:370 [Feb. 20] 1936), reporting a small series of cases in 1936 also favors the pack and windlass method. However this form of treatment has not been used at the Rotunda since 1920.

When Gibbon FitzGibbon became Master of the Rotunda in 1920 he modified the treatment, introducing the method now used in Dublin: the membranes are ruptured, a tight abdominal

binder is put on, and if the patient is not in labor, 3 minims (0.2 cc.) of solution of posterior pituitary is given every fifteen minutes for four doses. In 1926 FitzGibbon (*J Obst & Gynec Brit Emp* 33:194, 1926) reported sixty-four cases with three deaths. Since the introduction of the newer treatment the mortality from abruptio placentae has been consistently low, much lower than at any other time in the history of the Rotunda. The method is fully described in the latest editions of textbooks written by Dublin obstetricians: Solomons and Falkner (*Textbook of Obstetrics*, New York, Oxford University Press, 1937) and O'Donel Browne (*Manual of Obstetrics*, Baltimore, Williams & Wilkins Company, 1937).

Dr. Andrew H. Davidson, present Master of the Rotunda, writes: "The method of packing the vagina and applying a tight binder was introduced into the Rotunda by Sir William Smyly many years ago, and was in vogue until Dr. FitzGibbon came. He changed the method to the present one, and it is a very rare case that requires packing." In fact, the present teaching in Dublin is that packing is contraindicated, since solution of posterior pituitary given after tight cervical and vaginal packing may cause rupture of the uterus.

Previous to 1920 the mortality from abruptio placentae at the Rotunda was never below 15 per cent. In FitzGibbon's series of cases the mortality was 4 per cent. From August 1928 to October 1936 there were admitted to the Rotunda 255 cases of premature separation of the placenta. The total mortality rate was 4.7 per cent (Rotunda Reports, 1929 et seq.). Bethel Solomons, Master of the Rotunda in 1929, makes the following statement in his report for that year: "It cannot be too strongly urged that even an apparently moribund patient will recover with routine treatment and vaginal packing is scarcely ever indicated."

Syracuse, N. Y.

MODE OF ACTION OF SULFANILAMIDE

To the Editor—The article by Dr. Osgood and Miss Brownlee (*THE JOURNAL*, January 29, p. 349), reporting an investigation of the mode of action of sulfanilamide by use of their marrow culture technique represents an important contribution to the literature on this subject. Culture of the bone marrow provides a favorable device for investigating the reactions of these cells both to sulfanilamide and to the beta type hemolytic streptococci, alone and in combination. Especially interesting is the observation of the authors that living streptococci and marrow cells can exist together in culture for days without damage to the cells provided a sufficient concentration of sulfanilamide is maintained. However, it does not seem necessary to postulate any direct action of the drug on the toxins of this organism in order to explain this action especially since a bacteriostatic action of the drug has not been excluded by their experiments. Their results and those of Colebrook, Buttle and O'Meara and of Long and Bliss which they quote as favoring their hypothesis, can be adequately explained by an inhibitory action of the drug on the reproductive rate of the organism, such as has already been demonstrated by Long and Bliss for *Clostridium welchii* in mice. The authors also demonstrated this action but failed to give it proper evaluation in considering the action of sulfanilamide. Furthermore, the experimental data given in the paper do not show that the destruction of the marrow cells is due to toxins of the beta streptococcus, since experiments were not carried out with filtrates from cultures of this organism, either with or without sulfanilamide to determine the effect on the marrow cells in the absence of organisms. Lacking such data, the authors' results do not support their conclusion that the primary action of sulfanilamide is a neutralization of toxin in the case of the beta streptococcus.

Another point which has not been considered is that a slowing of the metabolism of the organisms, reflected by a slower rate of reproduction might also account for a diminished pro-

duction of toxic substances. Such an action would explain the authors' observation of some decrease in the size of hemolyzed areas about colonies produced by organisms which had been exposed to sulfanilamide.

The thesis that the elaboration of an exotoxin by an organism is necessary to the action of sulfanilamide against that organism has not found support from unpublished work in this laboratory on a non-toxin producing organism, *Bacterium necrophorum*. The virulent bovine strain used in these experiments causes an invariably fatal disease in rabbits. However, the infection can be controlled and cure can be brought about by treating the infected animals with sulfanilamide over a period of a week or more. Although we have not determined the mechanism as yet, it obviously cannot be due to the neutralization of any toxin.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

GOUT

To the Editor—My father has been suffering with recurring attacks of joint pain for the past ten years. The first attack involved the left big toe which became swollen, red, tender and very painful. At this time a diagnosis of gout was made and confirmed by x-ray examination of the toe and uric acid determination of the blood. He was given a purine free diet which he has used ever since but in spite of his guarded diet he has had yearly attacks of joint pain. The attacks usually occur suddenly and at night. At times he can predict the onset of the attack by slight pain in the joint. Usually only one joint is involved but at present he is suffering with pain in the left wrist and right ankle. After the acute attack the involved joint remains stiff for some time. At no time has any elevation of temperature been noted although the affected joint is much warmer. The joints most frequently involved are the left big toe, left ankle, left wrist and right elbow. He is 52 years old and a merchant. He is a hard worker and of a nervous type. He has always been troubled with constipation and indigestion (sour stomach and heart burn). For the past two years he has had severe frontal headaches lasting from twenty-four to forty-eight hours. In 1923 he passed two stones and in 1933 x-ray examination of the kidneys showed two kidney stones in the left kidney. A tonsillectomy was performed in 1923. A Wassermann test of the blood in 1933 was negative. X-ray examination of the teeth and sinuses gives negative results. Physical examination is negative except for a hypertension varying from 160/110 to 180/115. The heart is slightly enlarged to the left. The second aortic sound is greater than the second pulmonic sound. The lungs are clear. The abdomen is normal. The prostate and seminal vesicles are normal. X-ray examination of the feet shows an area of rarefaction on the head of each metatarsal which has the appearance of gout. Blood examination shows 4,580,000 red cells, 4,200 leukocytes and 90 per cent hemoglobin. The urine has a specific gravity of 1.022 and shows 1 plus albumin, a few epithelial and pus cells and occasional hyaline casts. A uric acid determination during an acute attack revealed 2.6 mg per hundred cubic centimeters of blood. The nonprotein nitrogen is 40 mg per hundred cubic centimeters of blood. Gastric analysis at sixty minutes reveals free hydrochloric acid 41 degrees and total acidity 61.5. What can be done to prevent future attacks of joint pain? What foods must not be eaten? What is your opinion as to eating small amounts of meat, drinking coffee or taking small amounts of wine with the meals? Are there any vegetables that contain uric acid? Is cinchophen the drug of choice and if so how should it be given to avoid damage to the liver? What is the significance of normal uric acid determination in an acute attack of gout? What part does the kidney play in this case? M. D. Colorado

ANSWER—It is assumed that peripheral subcutaneous tophi are not yet present. Whether they are present or not the history is consistent with a diagnosis of acute recurrent gouty arthritis. It is possible for patients to have a normal uric acid concentration in the blood during an early acute attack. As the disease progresses hyperuricemia becomes more obvious and more chronic. A value of blood uric acid as low as 2.6 mg per hundred cubic centimeters during an attack is unusual. Indeed it is low even for a normal person. It is suggested that estimations be repeated possibly checked in different laboratories.

Gout exhibits a seasonal effect becoming acute particularly during the spring (February-May) and autumn (August-October). During these months, patients should be particularly careful to avoid the various provocatives of gout they should adhere to their diet probably take cinchophen intermittently and avoid unusual trauma such as excess activity (from such as long walking or long automobile driving). The amount of physical and recreational activity to which the patient is accustomed can generally be indulged in with impunity if it is the unaccustomed amounts (often indulged in during vacation) that may provoke an attack.

During an acute attack a patient with gout should be on a purine-free diet. After the attack is over he should continue on a purine-low diet four or five days a week and a purine-free diet two or three days a week. A diet list used in one American clinic where many patients with gout are seen is as follows:

| 1 Food that contain a large amount of purine | 2 Foods that contain a moderate amount of purine (a) | 3 Foods that contain no purine |
|--|---|---|
| Sweetbreads Liver Kidney Squab Oysters Calf's tongue | Chicken Mutton Beef Oysters Herring | Milk Eggs Cheese Caviar Shad roe Nuts |
| Turkey Pork Veal Sausage Beef Goose Anchovies Sardines Trout Pike Perch Codfish Lentils Gravies Meat extractives Meat soups | Salmon Lobster Crab Whitefish Asparagus Lima beans Navy beans Kidney beans Kohlrabi Onions Pears Spinach Mushrooms Oatmeal Whole grain cereals— such as cooked whole wheat and wheat biscuits Whole-grain bread— such as whole wheat and graham bread | Gelatin Sugar and sweets Coffee Tea Lecor Fats of all kinds Fruits of all kinds Cereals (except whole grain) Bread (except whole grain) Vegetable soup (made without meat) Vegetables of all kinds except those listed in column 2 such as Lentils Spinach Mushrooms Peas Lima beans Navy beans Kidney beans Kohlrabi Asparagus Onions |

* Contain practically
no purine as served

It is generally recommended that patients whose gout is moderately active confine their foods largely to those in column 3, eat one selection daily from foods listed in column 2, avoid foods in column 1 entirely and eat one selection from foods in column 1 b on rare occasions only, perhaps once every one or two weeks or less often depending on the severity of their gout. Moderate amounts of coffee and tea are permissible. All wines and liquors should be avoided although they contain no purines or only minute amounts they adversely affect gouty patients with unusual consistency.

The majority of physicians interested in gout in this country regard the intermittent use of cinchophen necessary for the adequate control of the gout in most cases (Hench P. S. Diagnosis and Management of Gout in Certain Parts of the United States *Proc Staff Meet Mayo Clin* 12:262 [April 28] 1937). It is not certain whether liver damage from cinchophen can ever be completely avoided in the susceptible individual regardless of the method of administration. However the great majority of persons including patients with gout are apparently not susceptible to cinchophen and can take it repeatedly with impunity. Graham's (*The Treatment of Gout* *Proc Roy Soc Med Sect Therap & Pharmacol* 20:1 1937) method of administration is as follows: 7½ grains (0.5 Gm) three times a day for three or four consecutive days each week. When the patient is taking cinchophen he should also take from 1000 to 1500 cc of fluid daily and enough alkali to alkalinize each specimen of urine voided (e.g. sodium bicarbonate two teaspoonfuls in the morning and one or two in the evening). Some recommend also that generous amounts of carbohydrate be taken on the days when cinchophen is used.

Early signs of susceptibility to cinchophen are gastro-intestinal upsets (nausea) and hives or other skin reactions. With the appearance of these symptoms which seem to be due to the cinchophen (and not to the alkali) cinchophen should be stopped probably permanently. Some believe that hives do not afford a permanent contraindication to cinchophen in the case of gout patients who cannot control symptoms otherwise and that hepatic susceptibility, does not necessarily accompany skin susceptibility. They recommend the continued use of cinchophen.

in smaller doses. When the more serious signs of cinchophen toxicity appear (loss of weight, dyspepsia, icterus, pruritus), administration of the drug should of course be stopped immediately and appropriate therapy started (intravenous dextrose, high carbohydrate diet, generous fluid intake). The results of such treatment are now usually satisfactory and fatal cases of cinchophen toxicity are becoming fairly rare.

There is no established pharmacologic substitute for cinchophen. In general, the amounts of salicylates necessary to reproduce the effect of cinchophen on urate excretion are so large that gastro intestinal irritation and sweating are induced. Colchicine has no effect on urate excretion. Recently Hench (as cited) and Rutledge and Bedard (Criteria for the Diagnosis of Presumptive [Pretophaceous] Gout: Management of an Illustrative Case *Proc Staff Meet Mayo Clin* 12:149 [March 10] 1937) have noted preliminary clinical observations on the synergistic action of salicylates and aminoacetic acid on urate excretion and have suggested that this combination may prove to be an effective substitute for cinchophen. This is supplemental to the physiologic observations of Quick (Relationship Between Chemical Structure and Physiologic Response: Conjugation of Salicylic Acid with Glycine and Its Action on Uric Acid Excretion *J Biol Chem* 101:475 [July] 1933).

Patients with moderately advanced or late gout frequently develop kidney stones or gravel with or without frank nephritis. The gravel or stones are usually almost pure urates and are not opaque, and hence they are not visible in ordinary roentgenograms. Stones which ordinary roentgenograms reveal must be of mixed composition. Urate stones can be revealed only as nonopaque islands in the opaque shadows produced by intravenous (or other) pyelograms. The purpose of giving alkali during cinchophen administration is to prevent urates which are being excreted in excess from precipitating as stones or gravel in an acid urine.

COMPLEMENT FIXATION FOR WHOOPING COUGH

To the Editor—Please send me information on the complement fixation test for whooping cough. What is the technique?

J. C. CHAPMAN, M.D. Birmingham, Ala.

ANSWER—Daughtry-Denmark, since 1933, has used the complement fixation test technique for diagnosis, and after vaccination with the customary total dosage of 8 cc of authorized B pertussis vaccine (*Am J Dis Child* 52:587 [Sept.] 1936). To secure complete complement fixation, some children require a total dosage of 11 cc occasionally 14 cc. E. L. Webb (serologist, Georgia State Department of Health, Atlanta), uses the following technique:

The procedure follows closely Kolmer's qualitative test for syphilis. The only difference in the application of this test to specimens to be examined for syphilis and those to be examined

Details of Procedure

| | Unknown Positive and Negative Controls | | | Reagent Controls | | |
|--|--|--------|--------|------------------|------------|------|
| | Tube 1 | Tube 2 | Tube 3 | Anti-gen | Hemo-lytic | Cell |
| Saline solution | 0.1 cc | 0.1 cc | 10 cc | 0 | 10 | 20 |
| Patient's serum | 0.1 | 0.1 | 0.2 | 0 | 0 | 0 |
| Antigen suspension 1/2 anticomplementary unit | 0.1 | 0.1 | 0 | 10 | 0 | 0 |
| Complement solution 2 full units | 10 | 10 | 10 | 10 | 10 | 0 |
| Place in refrigerator at 6 S C for 14-18 hours (over night) and then in water bath at 37 C for 10-15 minutes. Remove and add | | | | | | |
| Amboceptor solution 2 units | 0.1 | 0.1 | 0.1 | 0.1 | 0.1 | 0.1 |
| Sheep cell suspension 2 per cent | 0.1 | 0.1 | 0.1 | 0.1 | 0.1 | 0.1 |
| Shake well and place in 37 C water bath for one hour (ten minutes after serum antigen and hemolytic controls are completely hemolyzed may be substituted). Remove and read results immediately or store in refrigerator three or four hours for later reading. | | | | | | |

for whooping cough lies in the antigen. This antigen composed of the killed B pertussis in suspension, is furnished by Eli Lilly Biological Laboratory, Indianapolis.

The same unit of complement is taken as that determined in the titration preparatory to the performance of the complement fixation test, on specimens of blood submitted for the examination for syphilis.

The dosage of the pertussis antigen employed is one third of the anticomplementary unit determined by titration. For instance, if the anticomplementary unit of the pertussis antigen is 0.5 cc of a 1:5 dilution, 0.5 cc of a 1:15 dilution is employed in the test.

Because the anticomplementary activity of this antigen gradually increases with age even though stored in the refrigerator, small fresh lots of the antigen should be supplied at frequent intervals.

Any laboratory equipped for Wassermann testing can perform this test. The required blood (15 cc or more) is obtained from an arm vein or from the finger tip. After the skin has been cleansed with alcohol it is dried with sterile gauze, several deep pricks are made close together with a sharp Hagedorn needle, the blood drips into a small, sterile centrifuge tube plugged with sterile cotton and labeled; it is refrigerated until the serum is removed. Complement fixation is considered diagnostic if 4-plus after completion of the prophylactic vaccine injections, it is considered an index of immunity. It should be performed soon after completion of the customary total dosage of vaccine. If the reaction is not 4-plus, an additional 3 cc of vaccine is given and the test repeated until complete fixation occurs.

SEA SALT BATHS—COD LIVER OIL IN SUMMER

To the Editor—1. Is there any beneficial effect obtained by bathing infants and children in sea salt at home? 2. Is there any contraindication to the administration of cod liver oil to infants during the summer season?

M. D. PENNSYLVANIA

ANSWER—1. There is no reliable experimental or clinical evidence to indicate that there is any beneficial effect obtained by bathing infants and children in sea salt at home. It has been loosely stated that sea water has a tonic effect through its mild counterirritant action in stimulating the peripheral circulation. However, the consensus among physical therapists is that the temperature of the water, rather than the content of salt, is the significant factor determining the amount of hyperemia of the skin. A salt rub, however, preceding a bath, of course produces hyperemia of the skin.

2. There is a deep-rooted belief in the public mind that cod liver oil causes digestive disturbances in hot weather. Cod liver oil in the usual dose of one teaspoonful three times a day rarely gives rise to digestive disturbances in hot weather in infants who can tolerate it at other seasons. However, digestive disturbances such as vomiting or diarrhea would constitute a temporary contraindication to its administration at any time of the year. An infant does not require as much cod liver oil during the summer because of sun baths but at least a teaspoonful daily should be continued during the summer, because after an interruption in its administration for several months difficulty in getting the child to take it again may be encountered.

DIAGNOSIS OF CANCER FROM URINE

To the Editor—In the June 1937 edition of *Modern Medicine*, volume 5, no. 6, page 66, I note an advertisement by the William Dunkler Laboratories of Chicago in which they offer a simple and reliable clinical laboratory diagnostic set to physicians for various procedures. Among the tests which can be performed by the physician with this set is early diagnosis of cancer from urine. Can you enlighten me as to the details and reliability of this test and the technique in performing it? As a laboratory man naturally I am interested but dubious. In following recent clinical literature I have not seen reports of any such test that is out of the experimental stage.

WILLIAM COOPER, M.D. Los Angeles

ANSWER—The request apparently refers to the Aron test, which has been the subject of much discussion and considerable criticism. Aron has published a large number of papers, chiefly in the French journals, in which he makes the claim that the urine of those suffering from cancer when injected intravenously into the rabbit causes characteristic alterations in the adrenal gland. In the *American Journal of Cancer* are abstracts of papers by Aron and Aron, Stolz, Weiss and Kuntzmann (29:159 [Jan.], 30:164 [May] 1937), all of which are fairly favorable. Aron's latest technique is to precipitate from 1,000 to 1,200 cc of urine. The precipitate is dried in a vacuum and dissolved in physiologic solution of sodium chloride. The rabbits are then given intraperitoneal injections of 5 cc each receiving a number of such injections. On the other hand Desvry and Coheur (abstr. *Am J Cancer* 26:212 [Jan.] 1936) find the method to be without value and the same is true of Roussy, Oberling and Guerin (abstr. *ibid.* 24:867 [Aug.] 1935). Aron replies (abstr. *ibid.* 24:868 [Aug.] 1935) that there are certain serious sources of error, which he hopes to remove. The changes which he notes are diminution in size and the lipid of the spangiocytes. It is obvious from such contradictory statements that the method has still so many errors that it is of little use. There is no procedure in which a "simple and reliable" clinical laboratory diagnostic set will permit the early diagnosis of cancer from the urine and there is no reason to believe that there is any "simple and reliable" test for cancer in general.

COLON BACILLUS CERVICITIS

To the Editor—A patient almost a year ago had an acute cystitis which proved on culture to be of colon bacillus origin. This cleared up rather promptly but almost at the same time she began complaining of backache, pain in her right side (right lower quadrant) and dyspareunia. A little later she began to have an increasing amount of discharge. (She had never had any before.) Usually the discharge is nothing but clear mucus but at times it is whitish. Sometimes she will have cramps and then notices considerably more discharge. Microscopic examination of the discharge shows a few epithelial cells and only one kind of organism—a gram-negative rod which I am sure is the colon bacillus. A smear from the cervix contains so many of these organisms exclusively that it looks like a pure culture. Another peculiar thing is that there has never been more than two or three pus cells per field. I am absolutely positive that the patient has never had gonorrhea but clinically it looks like low grade salpingitis. The time of onset—at the same time as the cystitis—also seems to indicate colon bacillus origin although I never heard of it. The patient sometimes has a low grade fever up to 100 F and once or twice a leukocytosis of 14,000. Vaginal examination reveals little except tenderness in the right fornix and pain when the uterus is moved. Is there such a thing as colon bacillus salpingitis? If there is such a thing what can I do about it or what is the treatment?

M D Ohio

ANSWER—Rather recently it has been suggested that chronic infection of the cervix is important in the etiology of persistent vesical discomfort and that eradication of the cervical disease is accompanied by cessation of the urinary tract symptoms. This is a rather revolutionary view, somewhat contrary to accumulated experience.

This case may belong in that group. Yet it would appear more logical to assume that infection was first present in the urinary tract, the genital infection occurring secondarily—not the reverse. Colon bacillus infection of the fallopian tubes seldom develops as an independent clinical entity. It may occur as an aftermath of instrumentation of the cervix or as a complication of stricture of the cervix. The colon bacillus is seldom found in simple gonorrheal disease of the tubes but it is usually present in cases of persistent tubo-ovarian abscess.

In treatment, adequate cervical drainage is important. It has been suggested that if there is no localized palpable mass the administration of sulfanilamide may be indicated. However, the use of this drug in miscellaneous urinary infections and mixed surgical infections without careful bacteriologic study is not to be commended and a report of the treatment of such cases without detailed bacteriologic investigation lacks scientific value. Far more evidence is needed to warrant the use of sulfanilamide for infections caused by *Bacillus coli*, *B. typhosus* and *B. paratyphosus*. If this therapy is attempted and fails, painstaking search for undrained pelvic foci should be made.

CHRONIC RECURRENT CANKER SORES

To the Editor—A woman aged 25 complains of canker sores of the mouth involving the lips, the buccal surfaces, the tongue and the gums. These may be single or multiple and vary in size from 2 mm to 8 or 10 mm in diameter. They occur sporadically and are quite painful. The silver nitrate cauterizer relieves the pain and healing occurs in approximately two weeks. They have been present for at least fifteen years. Could this be a purely local phenomenon? What systemic conditions are associated with lesions of this type? There is no anemia. Elimination diets have proved ineffective. Supplemental vitamin therapy has also failed.

PAUL J. HEIDRICK, M.D., Wilber, Neb.

ANSWER—Although 'canker sores,' or aphthae were first described by Hippocrates some 400 years before the birth of Christ, accurate knowledge concerning them is still very meager. These lesions are a maculofibrous stomatitis and the case described would seem to fall into one of two groups: (1) habitual aphthae or (2) chronic intermittent aphthae.

1. Habitual aphthae constitute the dyspeptic canker sore and have been thought by some workers to be a low grade infection and by others have been considered allergic. Deficiency of vitamin B has been mentioned as a possible cause. The fact that dietetic treatment and vitamin therapy have failed to be effective in this case would seem to place it outside this group, but the allergic possibilities should be thoroughly worked out before a definite decision is made.

2. Chronic intermittent recurrent aphthae were first described by Mikulicz in 1888 and have been called Mikulicz's aphthae. This disease occurs primarily in women and not infrequently has its onset at the time menstruation begins. It tends to recur at intervals of from four to six weeks and the lesions are quite compatible with those described in this case. Nothing definite is known concerning the etiology. Many theories have been advanced but up to the present time all of them are purely speculative. No specific treatment is known. Local treatment with 5 per cent chromic acid solution or with alum or silver nitrate is recommended. It is not wise to allow the patient to use the silver nitrate stick because crater-like scars may result.

Occasionally dermatitis herpetiformis will produce lesions of the mucous membrane of the mouth, but the associated lesions of the skin serve to make the diagnosis.

It would seem that the fifteen years duration would fairly well rule out serious systemic disease and would be a positive argument in favor of considering this as a local phenomenon, probably a case of Mikulicz's aphthae.

DYSENTERY WITH GIARDIA

To the Editor—A recent patient had symptoms of dysentery. I had a stool examination made with the following report: Green produced streptococci and cysts of *Giardia lamblia* found. Literature on treatment of the latter is rather scanty—the only advice is neosarsphenamine. I am using mapharsen 0.04 Gm every five to six days with some improvement. I will appreciate any advice you may give.

M D Michigan

ANSWER—Many therapeutic agents have been used in the treatment of patients harboring *Giardia lamblia*. The best opinion today supports the belief that the newer arsenicals give the best results. A procedure that has enjoyed approval is to give the patient 0.25 Gm of treparsol (meta amino para oxyphenyl-arsenonic acid) three times a day for four successive days. The patient then waits eight days and repeats the treatment, again waits eight days and again repeats the treatment. Under such a regimen most patients will be freed of their *Giardia* cysts at the end of the third course of treatment. It must be borne in mind that 25 per cent of patients will have some toxic manifestations caused by the arsenic, and in such cases treatment must be discontinued immediately.

It is by no means certain that *Giardia* is the cause of dysentery for there is no general agreement on this point. Evidence based on pathologic studies, or even careful clinical evaluation of cases has not conclusively demonstrated that this parasite is the cause of either diarrhea or dysentery. The presence of green-producing streptococci in feces may be considered normal since most of the enterococci produce green pigment on blood agar plates.

It is suggested that a further study of the patient should be made before concluding that the cause of the dysentery is explained by the presence of *Giardia*.

HEREDITY OF DEAF-MUTISM

To the Editor—What are the hereditary possibilities for the offspring from a normal man whose parents are both deaf-mutes?

M D Ohio

ANSWER—Hereditary deaf-mutism is almost certainly inherited as a simple mendelian recessive. If this is the case deaf-mutes are homozygous pure for the deaf-mute gene and a mating of two hereditary deaf-mutes could not produce normal offspring.

On the other hand it is estimated that only from one third to one fourth of deaf-mutes are of the hereditary sort. It is well known that many infants are born deaf as the result of prenatal infection or become deaf as the result of infantile disease. Meningitis, scarlet fever and syphilis cause many cases of deafness. This type of deafness is not hereditary. If one or both of the mated deaf-mutes is of the nonhereditary sort only normal offspring are to be expected for all would inherit the gene for normal hearing from the parent with nonhereditary deafness.

WASTING DISEASE OF PIGEONS

To the Editor—There is a disease in pigeons which is characterized by wasting, prostration and green and watery stools. It is called 'light' or 'policomelitis'. I am interested in finding out the name and dosage of the drug that is given orally for this condition.

M D New York

ANSWER—The symptoms described are common to several pigeon diseases and similarly the term 'light' is applied to many diseases associated with emaciation. Of the parasitic diseases that cause these symptoms two nematodes, *Ornithostrongylus quadriradiatus* or *Capillaria columbae* might be involved. The former is about half an inch in length thin, and reddish in fresh specimens. It is most numerous in the first half of the intestine and causes an acute enteritis. The second species is about an inch long of the diameter of a hair and white. Infestations are apt to be more chronic. This parasite is difficult to see unless the intestinal content is suspended in water.

Nothing is known about the treatment for these parasites. However since they are nematodes tetrachlorethylene might be of value if the infestation has not produced induration. On the basis of what is known about the disease for chicken one should

not exceed 0.25 cc of the drug. One should attempt to control these parasites by sanitation. Transmission is simple and direct, so that clean dry pens or wire floors and isolation of affected individuals should accomplish much.

There is also a bacterial disease that attacks young birds by preference and causes diarrhea and emaciation. Occasionally nervous symptoms are exhibited and not infrequently infection localizes in the joints of the wings or legs. The causative organism, a member of the paratyphoid group, is *Salmonella aertrycke*. There is, of course, no treatment, but since the infection is often transmitted through the egg, some progress can be made by eliminating the carriers detected by an agglutination test. Rigid sanitation should also be practiced.

DIATHERMY AND OTOSCLEROSIS—STUFFY SENSATION IN EARS

To the Editor—1. What is the present consensus on the value of medical diathermy applied to the ear or mastoid in the treatment of otosclerosis of the familial or hereditary type? 2. Many patients complain of a numb dead or stuffy feeling in the ear although on examination no wax is present and the ear inflates normally on the Valsalva experiment. Is there any explanation of this sensation?

M D England

ANSWER—1. Medical diathermy is useful for one purpose and that is the production of heat. Applied to the ear or the mastoid in the treatment of otosclerosis of the familial or hereditary type it can only produce heat and there is no evidence that heat is of the slightest use in the treatment of otosclerosis.

2. A numb dead or stuffy feeling in the ears is frequently complained of by people who are deaf. This complaint is seen just as often in those who have a perception or auditory nerve type deafness. It is possibly the patient's way of saying that things sound distant or muffled.

INFECTIONS OF EXTERNAL AUDITORY CANAL

To the Editor—I will appreciate any information on the treatment of swimmer's ear or fungous infection of the external auditory canal. I have a case that is stubborn and quite extensive. It cleared up once but recurred after about three days and was much worse than the first attack. The last attack has lasted thirteen days and there was excessive serous discharge from both ears and vesicles on the outer ear and cheek which is still present to some extent. What is the treatment and what are the chances of recurrence?

M D Nebraska

ANSWER—The treatment of fungous infection of the external auditory canal consists of instilling on the affected side some 2 per cent salicylic acid in 95 per cent alcohol several times a day for a week or so. As a rule, the use of these drops is highly efficient. If the fungus has penetrated through the membrana tympani to the middle ear, the condition may become more stubborn and will require more in the way of local cleansing and the instillation of medicaments. The diagnosis of fungous infection of the external auditory canal is made by microscopic examination and the demonstration of the presence of aspergilli of one type or another. The description given does not correspond to the usual appearance of otomycosis. If microscopic examination fails to demonstrate aspergilli, the case described may be considered to be streptococcal dermatosis of the ears (Vitchell, James H. Streptococcus Dermatoses of the Ears, *THE JOURNAL* Jan 30 1937 p 361).

PREPARATION AND PRESERVATION OF COCAINE SOLUTION

To the Editor—Please advise me regarding the best method to use in preparing cocaine solution for nose and throat work. I find that after it stands a short time a cloudy material forms.

M D Pennsylvania

ANSWER—Cocaine solution made from freshly distilled water with from 1 to 3 thousandths parts of tricresol added as a preservative keeps in good condition for a long time. The preservative is added because cocaine solution should not be sterilized by heat for the salt is decomposed at a temperature of 98°C. The cloudiness that appears in such solutions is probably due to mold.

HYPERPLASIA OF SINUSES

To the Editor—From x-ray examination of my sinuses a hyperplasia of all of the sinuses has been diagnosed. Some being involved more than others. In stead of surgical intervention I would like your opinion on the possible application of x-rays to my sinuses. I am doubtful about surgery.

M D California

ANSWER—Neither the literature nor communication with accepted authorities lends any support to the idea that x-rays used in a therapeutic manner are helpful in a condition such as described.

A Plan of Introduction to Clinical Medicine Some Variations in Curriculum of the Third and Fourth Years in Medical School

DR B O RAULSTON, Los Angeles. The question of how third year students may best receive their introduction to clinical work is not easily answered because of the various factors concerned. Opinion will differ from one faculty to another, and the facilities vary from one institution to another. In our school immediately following the second year, which includes six hours a week in physical diagnosis during the second semester, the whole class spends the first seven weeks of the summer (June 14 to July 31 in 1937) in the wards in the department of medicine, in the capacity of clinical clerks. They are in daily attendance from 8:30 a.m. to 5 p.m. except on alternate Saturdays and Sundays. A group of six or eight students is placed in each of seven units. The average capacity of the units is forty beds. In addition to the house staff and visiting physicians there is a half-time instructor in daily attendance on each unit whose sole responsibility is to direct and supervise the work done by the students. The abundance of material permits selection of patients to be assigned for this work. The clerk is required to do a complete "work-up," including routine laboratory work on each patient assigned to him. The instructor reads and corrects the history, checks observations in the physical examination and when these are approved by him they become a part of the permanent hospital record of the patient. Progress notes are required in accordance with the condition of the patient.

On one day each week an instructor from the department of ophthalmology visits each group of students and spends from one to two hours demonstrating conditions of the eye-grounds in patients being studied. Similar instruction is given weekly in the department of otorhinolaryngology. At the noon hour on four days each week there is a lecture for the entire class. These correspond to the course usually designated as "applied" or "pathologic physiology." There are no other set exercises. Clerks are not required to attend any formal ward rounds but are permitted to accompany the attending physicians on rounds if they choose. The instructors hold informal discussions with the groups concerning history writing, physical examination how to make intelligent progress notes, and many other topics that naturally arise in such work. Clerks are required to attend autopsies done on patients they have studied. While there is no assigned reading and no written discussions are required aside from those contained in the patient's record, students are advised concerning sources of information related to the problems presented by their patients. At the middle of the period the groups are shifted from one unit to another. In 1937 the average number of patients worked up per student for the seven weeks was thirteen.

The chief advantage in this plan is the fact that students are permitted to study patients under careful supervision and practically without interruption for a period of seven consecutive weeks. They are unanimous in stating that they learn more during this time than in other periods of equal length in the

third or fourth years. Members of the faculty also have been well pleased with the results of this summer work, which is looked on as a continuation of the course in physical diagnosis and is considered to be a part of the second year curriculum. No defense is made against taking seven of the fifteen weeks of vacation. The remaining eight week period is more than enough.

Two factors involved in such a clerkship deserve special emphasis. First is the number of available patients in proportion to the number of students. This ratio depends on the rate of turnover and is naturally smaller in private teaching institutions where patients are selected than in charity hospitals where many patients have chronic diseases and therefore must be hospitalized for a longer time. Private hospitals find it too expensive to maintain a medical service large enough to accommodate an entire junior class as clinical clerks at one time.

During the first semester of the third year the entire junior class is assigned to clinical clerkship in the department of medicine. There is not the freedom from interruption that was enjoyed in the summer. Each group has a one hour bedside clinic four days a week at which a student presents the record of one of his patients to a senior attending physician and the other members of the group. There is a one hour set exercise at noon each day. There are four hours of lectures per week in the afternoons, and one afternoon is spent in the morgue examining fresh tissues. An instructor from the x-ray department spends from one to two hours a week with each group reviewing and discussing examinations that have been made by that department on patients studied by the group. Having had the summer work, these students are able to follow this schedule and do a complete work-up of from one and one half to two patients a week, including written directions for treatment, differential diagnoses, and one topic a week concerning some phase of the problem presented by a patient. By the end of the first semester each student will have done a complete work-up of about forty patients, in addition to his attendance at set clinics, group conferences and lectures.

In the second semester, half of the class is assigned to the department of surgery and special courses in obstetrics, the other half to special work in the department of medicine. The experience of twenty-three weeks' clerkship in medicine enables the student to carry on the work in other departments with relative ease and success.

In the summer following the junior year the class is divided into four groups, each of which spends four weeks in the outpatient department in medicine, four weeks in practical obstetrics and seven weeks as vacation. The last group in obstetrics overlaps the regular school year by one week. By this plan the students have their introduction to outpatient work in the department of medicine at a time when they have few if any other responsibilities. They have ample time in which to study their patients and to read about the diseases encountered. They are also of great value in carrying on the work of the clinic. To complete their work in practical obstetrics during the summer is to avoid continuous interruption of the fourth year work by attending deliveries at all hours of the day and night. This also meets the demands of our department of obstetrics for having the students entire time for a minimum of four consecutive weeks.

In the fourth year the class is divided into three groups. Each group spends one third of the year as clinical clerks in the department of surgery, one third in the outpatient department in medicine, including four weeks of clerkship in pediatrics, and one third in special subjects including clerkship in psychiatry, set clinics in communicable diseases, syphilis clinic and dermatology clinic. The entire class attends set exercises at noon each day.

The results obtained by giving our students their introduction into clinical medicine by way of a clinical clerkship in the department of medicine encourages the faculty to continue this procedure. Crowding of the medical curriculum, waste of time by medical students during long summer vacations, and the results obtained by using half of the usual vacation time between the second and third and between the third and fourth years of medical school appear to justify continuation of the plan in this school.

Undergraduate Instruction in Preventive Medicine

DR J G FITZGERALD, Toronto. This article will be published in full in THE JOURNAL.

DISCUSSION

DR JAMES N BAKER, Montgomery, Ala. The practice of medicine is becoming more and more preventive, and unless the men who take up the burden when we put it down are trained so that they can appreciate the need of integrating their activities into the various social structures that are around them they will fail in the purpose for which medicine is created. That is a challenge which is coming to the medical profession. There are many problems which have an important preventive aspect which the practitioner of medicine in his daily routine must learn to solve, and unless there is complete integration between the forces of public health per se, the official forces of public health and the medical profession, we shall both fail in performing the responsibilities that are ours.

DR W S LEATHERS, Nashville, Tenn. I think the medical schools of the United States and Canada have made considerable progress during the past twelve years in providing instruction in preventive medicine and public health. It has been my privilege to keep in touch with what has been done to some extent, and I am sure that in the next decade or so most of the medical schools in this country will provide reasonably adequate teaching in this important phase of medicine. The second point is that I am sure Dr Fitzgerald does not mean to imply that in a systematic way the outline which he presents should be followed in some kind of didactic type of instruction. He has simply presented a comprehensive discussion with reference to many points that ought to be considered by medical educators in this particular field. I think we owe him a debt of gratitude. The third point is that I think the medical schools are obligated to pay more attention to this particular phase of teaching, because of the increase in knowledge in public health during the past fifty years. We know a great deal more about how to keep well now than we did prior to that time, and, unless we translate this knowledge in terms of application in the experience and outlook of medical students, medical education will fall short of the objective which it should fulfil. In view of this remarkable development in the extension of public health, the attitude of the public toward this phase of medicine and the fine contribution which the physicians can make, the outlook in this particular field is most promising.

Some Aims and Methods of the Undergraduate Teaching of Obstetrics

DR JAMES R MCCORD, Atlanta, Ga. Too many maternal deaths occur in the United States. There seems to be no one cause or factor responsible. Permanent improvement will be difficult of achievement unless there is a parallel improvement in the teaching of obstetrics in the medical school. Administrative officials of our schools and hospitals must realize that obstetrics is a major branch of medicine and deserves equal recognition with medicine and surgery. So long as we attempt to teach obstetrics without an adequate number of obstetric patients, just so long must our students be poorly prepared to practice the obstetric art. There seems to be no substitute for the actual delivery of as many women as possible by each student. It is of vital importance that these deliveries be constantly and competently supervised. Nor should this mean the witnessing of deliveries by large or small groups of students. The mechanics of labor can be mastered only by frequent continuous observation and examination during the entire labor. Outdoor services incompetently supervised do not offer such opportunity. It should be the aim of our schools to familiarize the student thoroughly with normal obstetrics. When he starts practice he will be able to recognize quickly the dangerous and abnormal. This quick recognition is probably half the battle. It might be said that the one or two intern years are for this purpose. However actual contact with obstetric patients must be backed by certain fundamentals in teaching. If the principles are mastered the student in his actual practice will easily be able to weave in the detail. One of the serious faults of obstetric teaching is the lack of rep-

tion This necessitates, of course enough obstetric hours I like to teach this repetition of fundamental principles by sending the student to the board and having him explain his answer to the entire class

At Emory University School of Medicine the course in obstetrics begins in the second semester of the second year The student is taught the complete antepartum examination This is done by lectures, quizzes, manikin instruction and finally the actual patient The entire third year should be devoted to the mechanism and management of normal labor and the puerperium and to the various anomalies of mechanism It is impossible to overemphasize this teaching The entire class meets two hours each week throughout the year Small sections attend the antepartum clinic and are given eighteen hours of individual instruction Repeated examinations of pregnant women give the student confidence in abdominal palpation The antepartum examination of many women teaches the student to become conscious of the diseases that frequently complicate pregnancy

During the senior year it is important that the student be familiar with material that has been previously presented We do this in several ways The class is divided into small sections For six weeks their entire time is devoted to obstetrics The fundamental in this teaching is again, actual contact with many patients both in the labor wards and in the antepartum clinics The group has a twelve hour manikin review on the mechanisms of labor and the operations of forceps and version are shown There is sixteen hours of conference quizzes with the professor of obstetrics Each student for eight hours every day is on active duty in the labor rooms He delivers all normal cases and is under constant supervision He is not allowed to leave the labor room and makes and records frequent observations and examinations of his patient His record is a part of the hospital record Under the supervision of an experienced labor room supervisor he is taught the preparation for vaginal examination and is required to do several Each student delivers from thirty-five to seventy-five women The student on inactive service for an eight hour period gives anesthesia for deliveries, does certain laboratory work of the ward, and accompanies the attending and resident physicians on ward rounds The group has sixteen hours in the newborn service with the professor of pediatrics They work in three antepartum clinics and one postpartum clinic weekly One of these is an antisyphilitic therapy clinic Intravenous arsenical therapy is given by the student under supervision There is sixteen hours for obstetric and gynecologic pathology Each student is furnished with a set of fifty slides illustrative of the more common pathologic conditions The entire class has two hours weekly of lectures and quizzes The subjects taught are the complications of pregnancy, labor and the puerperium Examinations for promotion and graduation are individual and oral

DISCUSSION

DR ANDREWS ROGERS Columbus, Ohio A few years ago at Ohio State we tried to put beginning obstetrics in the sophomore year, the last quarter, because at that time we wanted to introduce the juniors into the antepartum and postpartum clinics I had to fail approximately one third of the class There is a difference What those few months constitute, I don't know They associate with doctors, they associate with senior students They do something I had to rearrange the course Fortunately for those who failed, the course had to be given over again so they lost no time The next point I wish to mention is how to get more time more material and more accommodations, such as were recommended by Dr McCord I got it years ago when I started at Ohio State I worked night and day with the students patients group teaching and manikin instruction, and from the very first my whole plan and idea was to make it so attractive, so profitable to the future medical practitioners that they would demand and when the students demand one gets it

The Teaching of Nutrition to Students of Medicine

DR SALVATORE PABLO LUCIA and NINA SIMMONDS ScD, San Francisco This article will be published in full in THE JOURNAL

FEBRUARY 15—MORNING

DR CHARLES GORDON HEYD, New York, in the Chair SYMPOSIUM ON GRADUATE MEDICAL EDUCATION

CHAIRMAN HEYD For the last thirty years there has been created in this country a great public opinion on medical education and, without laws, without statutory regulation, there has been a constant improvement in the quality of medical education We look to the future with a larger labor before us, that of the continuing education of the physician after graduation and of the graduate studies There is no particular hurry that this great topic shall be settled in a few years If the object of eternity is to make perfection, it is obvious that we should go slowly In this work the American Medical Association will play its part as it has in the past without any national subsidy because as the late Mr Gladstone said, progress in medicine has been largely due to the fact that the medical profession has maintained its independence

Graduate Medical Education

DR IRVIN ABELL Louisville, Ky Graduate education may be divided into two categories one dealing with the preparation and training of specialists, the other dealing with the continued education of those who are not specialists The first category may be further subdivided into (a) the kind of training which is designed to prepare one for special practice and (b) the more advanced training which may be desired from time to time in order to keep the physician abreast of the latest developments in special and general fields Group a training under this category must be conducted chiefly in large cities or in large clinics with abundant material The twelve special examining boards for the certification of specialists have now established standards of training which are mandatory for those aspiring to be diplomates These standards demand clinical training for varying periods beyond the intern year Hospitals and clinics under university control now supply such facilities to a limited number but wholly inadequate to meet the demands of those aspiring to such training The immediate problem is to induce qualified hospitals to establish a system of graduate training and to stimulate the development in the medical schools of a consciousness of their educational obligation to the hospitals in their immediate communities and a willingness to enter into the graduate training program in hospitals other than their own The Council on Medical Education and Hospitals has designated certain hospitals as approved for the training of interns and residents without, however, specifying more than elementary requirements for such and without denoting the period of time to be consumed in such training It will clarify the situation to designate both the period of time devoted to, and the character of, intern training best suited to form the basis on which further graduate training is to be superimposed Also to determine whether rotating internships are desirable for candidates in all the specialties or whether internships in the specialties alone best prepare the candidates for continued study and training in their respective fields A survey of the hospitals approved for residencies shows that the period devoted to the residency varies from one to seven years, 70 per cent of the residents receive but one to two, and 30 per cent from three to seven years training Further, that the titles of the supposed resident are confusing, they being listed as resident, junior and senior residents assistant resident, senior and junior interns, house officer house physician and house surgeon Uniformity of nomenclature is desirable, criteria for the qualification of hospitals for graduate training are essential and a definitely planned schedule of training for the graduate is necessary

The second phase of the first category, the more advanced training which may be desired from time to time to keep the physician abreast of the latest developments in his special field, will of necessity find its exposition in the postgraduate schools and in the clinics and hospitals, the staff members of which are not only proficient in their respective fields but competent and able in imparting the newer principles and procedures of their specialty There are at present more than fifty medical schools which enroll graduate students, and of these an increasing number are planning courses for the review of both the

old and the new. Specialized hospitals and the general hospitals which are highly departmentalized, possessing an adequate average patient census comprised of the types of patients required and used for teaching purposes, can well fill this want, subject to the supervision of the Commission on Graduate Medical Education.

The second category, namely, further education for those who are not specialists, presents complex problems in aiding the doctor who desires to add to his medical knowledge and to improve his skill as a practitioner. It may be divided into two phases, intramural and extramural. The intramural phase consists of courses offered by medical schools and university connected hospitals and should include clinical experience in addition to bedside lectures and demonstrations. Such courses, organized on a basis of practical instruction, offer the best plan of elevating the standard of efficiency of the practitioner if he will but come and seek it. Of definite value are the courses offered under the auspices of the county societies and given in approved hospitals by competent staff members consisting of short series of demonstrations and clinical expositions covering topics which the doctor meets in his daily work. These plans necessitate the absence of the practitioner from his location and entail the expense of fees and upkeep, stipulations that many for various reasons feel unable to meet. The extramural phase, that of carrying graduate training to the practitioner, is complex and difficult. A vital objection to most of the plans now in operation is that, clinical facilities not being available, the instruction is wholly didactic. Text-book reviews are of doubtful value, while practical talks by experienced teachers possess definite utility, particularly if featured by clinical demonstrations. Each state medical association could place this phase of graduate medical education in the hands of an interested committee which would be charged with the responsibility of arranging the program of designating the centers and of selecting the clinicians. The program could be formulated with some idea of continuity so that definite subjects are assigned to stated meetings over a period of time, preferably on a yearly basis, or longer if desired. Certain cities or towns, strategically located over the state and by preference the site of a hospital or clinic, should be selected as centers with the idea of minimizing the time and inconvenience of the attendants. Clinicians to be selected from the medical schools and/or from the approved hospitals of the state should be of established reputation and competence in clinical teaching. The course or programs should be prepared with the aim of presenting the underlying and fundamental principles in each subject and their practical modern application. An interested local committee can and should provide clinical cases, which with demonstrations, illustrations and lantern slides afford the clinician the requisites for a clear and sound exposition of his subject. Conferences and round table discussions on the material presented will serve to elucidate many points and bring to the practitioner a better conception and appreciation of the difference between the old and the new. A statewide plan arranged along this or similar lines would involve no little effort but if faithfully carried out would bring to the vast majority of stay-at-homes medical education of genuine worth. To improve its standard of practice is a challenge to be met by organized medicine.

Opportunities for the Training of Future Internists

DR J. H. MUSSER, New Orleans. This article will be published in full in *THE JOURNAL*.

Continuing Professional Education

DR JAMES D. BRUCE, Ann Arbor, Mich. This article will be published in full in *THE JOURNAL*.

DISCUSSION

DR MORRIS FISHBEIN, Chicago. The speakers have outlined in each instance a commendable plan for the specialty that concerned them. In *THE JOURNAL* during the next twenty weeks we expect to have, each week, the plans of individual states, indicating how much graduate medical education is going on and has gone on in each state. These plans are developed largely under such systems as the one described by Dr Bruce which has been under the control of the state medical society, the university and other agencies correlated

within the state. Dr Bruce's presentation shows how it is possible for the physicians in any state, through their state medical society and their state university, to work out a suitable plan for carrying graduate medical education steadily forward. In the past thirty years the Council on Medical Education and Hospitals has spent well over a million dollars, in an endeavor to raise the standards of medical education in the United States and to keep them at an exceedingly high level. That has been done out of funds contributed by the American Medical Association through the income derived from physicians and from the publications of the Association without a request to the federal government, to the state government, to any philanthropic agency or to any other body, either for funds or for direction as to how the work is to be done. It has been done with the single motive of raising the standard of medical practice and providing better medical care for all the people of the United States.

DR TORALD SOLLMANN, Cleveland. I should like to discuss a point that concerns especially the medical schools, the requirement of the basic training in the specialist's training. As the proposals existed originally they seem to contemplate set courses for research in the basic sciences for all the different specialties, which would raise great difficulties for the medical schools. There are at present, I think, ten specialty boards. If the medical schools in their basic departments are to conduct ten courses for this specialty, that specialty, and so on, it would of course require a great deal of money and considerable additions to the staff. The money is difficult to obtain at this time, and the staff is impossible to obtain. The idea seems to be going around that every one going in for the specialties should be obliged to do a bit of research. I do not believe it is a good idea. Of course, the leaders in the subject certainly should have a research background, but to force a man who is going to practice a specialty in an everyday way to do research in which he probably has no particular interest, just for the purpose of securing a certificate, is, I think, a subversion of research. The proper approach to these specialties is the apprenticeship relation, where the master in the subject guides the studies of the one who is aspiring to become a practitioner of the subject. In that case the responsibility of laying out what work in the basic sciences he should do should lie altogether with the master. He should arrange the work, and a great deal of that work could be taken without arranging special courses. Dr Abell mentioned, where the medical school affiliations were not possible, that such an approach of the master-apprenticeship relation there might be a substitute. I think that perhaps when this relation is possible the substitute may be better than what seems to be conceived by some as the ideal method. There is no best method of reaching anything of this sort. There are several approaches, and they may all lead there, according to the individual.

CHAIRMAN HELD. As one reads the history of the development of medicine one can readily determine where certain influences came in that restrained the development and progress of medicine. It was when agencies of the government legalized the control of medicine through guilds, and it was a matter of record that men were prevented from practicing medicine because they doubted the infallibility of Galen. It is medical progress owes anything to influences that arose in society, it has been that the profession has been untrammelled in the development of its objectives. There seems to be an inhibitory to participate in extragovernmental functions with control in every division of human activity. It will be a sad day for society when there is placed from above an arbitrary control of bureaucracies that shall determine medical thought in this country.

The Rural Hospital An Educational Center

DR LESTER J. EVANS, New York. This article appeared in full in *THE JOURNAL*, March 26, page 945.

The Role of the Hospital in Advanced Professional Training

DR A. C. BACHMEYER, Chicago. A comprehensive program for the advanced training of the physician can be formulated and properly conducted only through the cooperative efforts of medical associations, medical colleges, state medical boards,

and hospitals The hospital should participate in a number of these activities, among which the following may be briefly enumerated (1) The internship (2) the residency in special services, (3) the clinic and the clinical pathologic conference, (4) the seminar, the round table or panel discussion and the staff conference, (5) the presentation of demonstrations and exhibits, (6) the lecture, either single or in series, (7) the exhibition of motion pictures, (8) the conduct of short courses of the refresher type, (9) the development of medical libraries, with lending privileges, (10) the development of laboratories for investigation and research, (11) the conduct of prolonged courses of graduate study requiring periods of residence at college and hospital

If the standards of medical practice in the institution, small or large, do not measure up to the requirements prescribed, the hospital is not providing proper service and certainly should not be permitted to undertake educational activities From this it would appear that our national societies are confronted with the serious and difficult task of elevating the standards of service in these many institutions

American hospitals with some exceptions are not educational institutions Boards of management frequently become perturbed when educational activities are proposed, though it is generally acknowledged that the conduct of clinical teaching in a hospital is a guaranty of a high standard of professional service It should not, however, be difficult to convince hospital authorities that in supporting educational endeavors their institution will be providing a more comprehensive service to the community than if they provide only for the immediate care of the patient, no matter how fine the quality of that care may be

There are 712 hospitals on the approved lists for intern training These institutions provide a total of 7,167 intern positions—far more than are ordinarily required each year for the graduates of the medical colleges Though, with few exceptions, all medical graduates are now serving internships in hospitals approved by the Council, the testimony of large numbers leads one to believe that the educational opportunities offered are far from satisfactory The deficiency lies in the absence of an organized program of training for the intern The situation merits particular attention for postgraduate education begins with the intern year There is first a need for an understanding of the purpose of the internship It is particularly during this period of the physician's career that he should be encouraged to undertake independent study and to develop his own initiative in constantly pursuing his education Although the exigencies of practice occupy the time of many staff members a larger number could devote more time to the needs of the intern and assist in his instruction if the necessities of the situation were brought home to them Leadership must be provided by the staff and the local medical society

Four hundred and thirty-eight hospitals offering 3,202 residencies in thirty-three divisions of medical practice, are approved by the Council on Medical Education and Hospitals The Boards of Medical Specialties have developed definite requirements for training during the residency There remains, however, great variation in the value of this training There is need for more organization as to content of service and opportunities for professional advancement

Though only a small proportion of the hospitals can participate in these first two steps of postgraduate education, every hospital in which medical practice is conducted on a proper plane can assist in the continued education of the physician It is this phase of the program that requires greatest development The local medical societies can be of great assistance In many communities their leadership and cooperative planning will be productive of greater accomplishments than if each hospital plans for itself and endeavors to develop a program without regard to the facilities and opportunities available in other institutions

DISCUSSION

DR AUSTIN A HAYDEN Chicago I was glad to note Dr Bachmeyer's emphasis on leadership in hospital administration and in intern training and medical education That leadership should be focused along the line of medical coordi-

nation of the various functions that hospitals and doctors are able to give the public, and to give the student as a teaching factor The classification of hospitals which Dr Bachmeyer used is good, but it doesn't go far enough For instance, in rural communities there are many agencies, aside from the hospital, the small hospital as a general rule, that should be taken into consideration It should be the purpose of the American Medical Association and the American College of Surgeons, and whatever other organizations attempt to standardize or regulate these institutions, to regulate them according to their locality and according to the possibilities for service and for regulation that they present I think hospitals might be divided roughly into rural, urban and teaching A rural hospital may be one or two beds up to a dozen beds in the back of a doctor's office It is possible for that hospital to render good service, provided it renders the service it is capable of rendering from the standpoint of its physical equipment and from the standpoint of its professional personnel I had the opportunity of visiting with Dr William Allen Pusey in Elizabethtown, Ky., a town of about 6,000 people Elizabethtown is a suburb really, of Louisville Elizabethtown also has suburbs, and one of those is Millersville To go to Millersville we had to cross three creeks There was no bridge and we went over on a ferry boat In Millersville there were about forty people, I imagine There was a drug store owned by a doctor, and some hospital facilities beds, microscopes, a considerable amount of laboratory equipment and such Across the street was a filling station which is also an adjunct of that hospital It has largely been made so by the publicized efforts of the American Red Cross, by which they had established certain first aid facilities, or attempted to do that, in filling stations Here you have the filling station, the drug store and hospital constituting the immediate medical facilities and hospital facilities of that town of forty or fifty people Those things are absolutely all right, and it would be a great injustice to the people of that community if any organization were to try to standardize things in such a way that it would discredit those small places If you hook Millersville up with Elizabethtown, and then hook Elizabethtown up to the hard road to Louisville with proper ambulance service—the proper ambulance doesn't need to be much more than a bed in an automobile—you have immediately equipped that little inland town with pretty fair hospital service and excellent medical service The urban hospital, in general terms, might be divided into the open staff and the closed staff, and a staff that is in between As usual the in-between proposition greatly outnumbers either of the others The closed staff would be represented in Chicago by institutions like the Presbyterian Hospital, where every man in attendance is a teacher at a medical school As Dr Bachmeyer says, the total number of beds under this classification of hospitals is small in comparison to the total number of other administered beds, but the function of that is definite in the teaching of undergraduate medical students But the open-closed the closed open (whatever term you like to use) hospital that has been approved is where the vast majority of interns will finally find their place Dr Bachmeyer properly said that the opportunities for special training in those is not to be compared with the opportunities in a larger hospital I saw, at St Joseph's Hospital this morning, a boy 15 years of age who woke up blind in the right eye about three days ago just out of a clear sky With that history, the thing that occurred to me was a retinal embolism He had a cherry macula and the retinal arterial circulation was practically blocked off I had every intern in the hospital look into that eye I have never seen a half dozen of those cases in my experience I told those boys the only thing they should know about that was possibly the ability to recognize it but, more important perhaps, to have the ability and the knowledge necessary to turn that over to some one who would see a few of those cases occasionally in other words the name address and telephone number of a competent individual who sees such things occasionally On the other hand in the routine things that come into hospitals in fair numbers they can be trained satisfactorily in a great many of the hospitals to which Dr Bachmeyer has referred

Book Notices

Practical Proctology By Louis A. Bule A.B. M.D. F.A.C.S. Head of Section on Proctology The Mayo Clinic Cloth Price \$6.50 Pp 512 with 152 illustrations Philadelphia & London W. B. Saunders Company 1937

The author has followed a well made outline in his discussions and has written a volume in clear, readable English, thoroughly punctuated with his personality. He has wisely avoided the encyclopedic type of textbook, as well as historical and theoretical temptations, and has recorded his own beliefs and his proved technic. The entire subject matter has been reinforced by the statistics of a large clinic and by the assistance and cooperation of many professional associates. In this way bacteriologic topics and the chapter on anesthesia, parasitology, therapeutics and surgical technic become complete and authoritative. Few photographic illustrations are used, fortunately, the text being well supplied with excellent diagrammatic illustrations made by experts in anatomic drawing. These enhance the value of the volume notably. The author has taken pains to differentiate between anal and rectal lesions and given a clear cut terminology of fistula. The willingness of the author to question established customs and practices and his ability to devise new procedures for operations on the rectum or anus are commendable and make for progress. However, there will be those who disagree with the dicta that local and spinal anesthesia should be taboo, that an approaching abscess should not be incised until near rupture time, that the injection of a fistula tract serves no end, and that the lithotomy position should be discarded. Pruritus ani is discussed sanely and with a complete review of the accepted methods of treatment. The etiology of this condition has resisted a favorable analysis. The author has made a noteworthy attention to the alcoholic injections for a relief treatment, probably overstressing its dangers and difficulty in application. The chapter should be read by every practitioner. The discussion of ulcerative colitis is voluminous and authoritative. It represents the combined efforts of a large group and reviews thoroughly the unfinished study of a large subject begun by Hale White in 1888. The colored illustrations in this chapter are especially instructive and completes the text to the satisfaction of the enterologist and the novice in medicine. The critical reader would have enjoyed a review of some of the obscure causes of pain referable to the rectum and anus as produced by coccycodynia, sacral neuritis and the pressure of chordomas. The volume is a distinct addition to proctologic literature.

Behind These Columns Mellon Institute Dedication of the New Building to Science and Humanity for Andrew W. Mellon and Richard B. Mellon. Boards Pp 55 with 24 illustrations Pittsburgh Pennsylvania 1937

This volume was prepared for the dedication of the new building of the Mellon Institute last year. It comprises a historical review of the institute and a summary of the work that has been done, and a description of the building. Robert Kennedy Duncan, a scientist interested in literary work, conceived the idea that was developed with the aid of the Mellons. Duncan attended the sixth International Congress of Applied Chemistry in Rome in 1906 and came back with the basic idea. He accepted the chair of industrial chemistry at the University of Kansas and there arranged for the first industrial fellowship. His writings attracted the attention of Andrew and Richard Mellon in 1909. Later he was invited to head a department of industrial research at the University of Pittsburgh, where the industrial fellowships began operating March 1, 1911, in a frame building with funds provided by the Mellons. This experiment was followed by the founding of the Mellon Institute of Industrial Research at the university in March 1913. Duncan was authorized to design a modern headquarters with laboratory facilities, but he died before the building was completed. The institute carried on its work as a part of the University of Pittsburgh until 1927 and since then it has been managed by its own board of trustees. The building which inspired the title of the book, is a beautiful monument to the founders. Mellon Institute is one of the first institutions in this country founded to blaze the

research trail for industries. It is a nonprofit organization, although part of the burden of research is borne by funds appropriated by individual firms which finance industrial fellowships. The research is organized on a contract basis. A problem is presented by a person or company interested in its solution and the scientist needed to solve the problem is engaged by the Mellon Institute. The fellow is given the broadest facilities for accomplishing the research. The institute has demonstrated to about 4,000 American companies that properly conducted research can be productive. Since 1911 there have been 1,150 industrial fellowships on 279 different subjects. About 650 novel processes and products have been invented or developed by the fellows. Some of them have afforded sufficient basis to create new industries and others sufficient basis to build new branches of existing industries. The chrome plating of aluminum was developed to commercial applicability at the institute. Butane gas for metal cutting operations, a dental cement, a moth-proofing agent, a process for the recovery of cuprous sulfide from copper ore, improved roofing materials, better varnishes, perfection of sodium metaphosphate as a boon to laundering, a new safety fuse, a shoe leather impregnated chemically to make it better wearing and many other products were evolved by fellowship researches. The institute maintains a department of research in pure chemistry. Some of the research bearing on public health has pertained to smoke abatement, the cause of dental caries, nutrition, immunology and industrial dusts. Since 1930 the Department of Research in Pure Chemistry has studied the cinchona alkaloids in cooperation with medical scientists in some of the hospitals in Pittsburgh. Research on the treatment of pneumonia in cooperation with a hospital has been in progress. The new home of the Mellon Institute will bring to bear more intensive effort in the fields of chemistry, biochemistry and biology, as well as in the field of pure science.

Health Insurance The Next Step in Social Security By Louis S. Reed Cloth Price \$3 Pp 281 New York & London Harper & Brothers Publishers 1937

From the first two paragraphs in the preface to the end of this work, Mr. Reed indulges in propaganda on behalf of compulsory insurance. He admits frankly that he is a propagandist and he apparently is influenced to modify the material if it fails to fit the propaganda. When he says that the "medical profession had taken an adamant position in defense of the status quo" he is stating an untruth and he is making propaganda. The author admits frankly that there is little originality in his work and that most of it is the outcome of his association with the Committee on the Costs of Medical Care, including I. S. Falk, Harry Moore, Nathan Smail and some of the others. Abraham Epstein has set him right on several points and Michael Davis has given him counsel and encouragement. From this array of alleged authorities in the field of medicine—not one of whom is a physician—the medical reader will know how to evaluate this work. The various employees who earned their livings from the Committee on the Costs of Medical Care during the term of its existence are continuing to turn this old material over and over squeezing the lemon to its last drop of juice. It would be a work of many hours and require a great deal of space to list carefully all the misrepresentations in this volume. For the high school students who are continuing to debate the subject of health insurance at the order of their teachers this volume should be a most useful reference work. Mr. Reed's answer to the problem of medical care is some system by which the people in the United States with incomes below \$3,000 a year will be compelled to save against the cost of sickness and will be helped by government money when the compulsion is madequate. His answer to the medical problem is therefore compulsory sickness insurance and federal subsidies. What happens to the democratic system of government under these compulsory systems does not apparently concern him. He is willing to begin slowly and he recognizes for example that any attempt to give the public satisfactory dentistry would bankrupt the system. Perhaps when an attempt is made to give all of the nation complete medical service at government expense these economists will discover that it is possible to bankrupt the nation.

The Sex Life Before and After Marriage By William S Sadler MD Director The Chicago Institute of Research and Diagnosis and Lena K Sadler MD Associate Director The Chicago Institute of Research and Diagnosis Volume I Sexual Hygiene Volume II Marriage Cloth Price \$2.95 per set Pp 129 133 334 Chicago American Publishers Corporation 1938

In these two volumes the authors have given the reader a comprehensive picture of the sex function and its relationships to individual living and to marriage. In the first three chapters consideration is given to the anatomy, physiology and biology of the sex impulse, following which the authors proceed to a discussion of masturbation and autoeroticism. At this point, in chapters 5 through 8, they deal with sexual deviations, abnormalities and neuroses, and in chapter 9 with venereal diseases. This chapter is followed by a glossary, which closes the first volume. In volume II are chapters covering the art of making love, the choice of a partner, courtship, marriage as an institution, the cultural and other factors in marriage outside of sex, marital sex experiences and special problems, principal sources of marital trouble, contraception and birth control, the menopause and an expression of their opinions with relation to the modern sex problem. The treatment is complete, exhaustive and for the most part, accurate. The discussion of how sex is determined is inadequate except to a reader who understands cell structure and cell division. The same criticism applies to the description of the Aschheim-Zondek test, in which the test is attributed to the pituitary hormone instead of to the placental hormone. Under the heading of "Venereal Disease Prevention," recommendation is made for the use of "Iysol" it would have been equally effective, and much more advisable, to use the designation saponated solution of cresol. The statements about the relationship of lactation subsequent to pregnancy are confusing, though a careful reading makes it evident that the authors wish to discredit the popular idea that lactation always prevents pregnancy. The male climacteric referred to in volume II, is not generally accepted. These should be useful and informative books for serious readers. They contain a good deal of repetition and appear to overemphasize the abnormal. Probably for the average reader the work would have been improved by greatly minimizing the references to the abnormal. The books are particularly to be commended for the conservative attitude toward Freudism, giving it due credit for contributions to methods of investigation and treatment of the neuroses but recognizing factors other than sex as a possible basis for the neuroses. The authors express a philosophy which endorses the monogamous conception of marriage and yet at the same time display a broad sympathy for individuals whose sexual problems and urges bring them into conflict with society. Their chapter on contraceptives properly emphasizes the one inescapable fact that there is as yet no completely reliable contraceptive method except abstinence.

The Laboratory Diagnosis of Syphilis The Theory Technic and Clinical Interpretation of the Wassermann and Flocculation Tests with Serum and Spinal Fluid By Harry Eagle MD Lecturer in Medicine Johns Hopkins University Medical School Baltimore With foreword by J Parlo Moore MD Associate in Medicine Johns Hopkins University Baltimore Cloth Price \$5 Pp 440 with 27 illustrations St Louis C V Mosby Company 1937

In his attack on the rather considerable task to which he set himself (as detailed in the subtitle) the author of this monograph maintains a high degree of objectivity. He does not attempt to 'prove' anything and thus succeeds in establishing a body of carefully documented facts and skilfully drawn conclusions which should be of great service to the practicing clinician and serologist, and of use to the investigator. The text is composed of a historical introduction six parts and five appendices, and concludes with a selected bibliography of approximately one thousand titles. Parts I and II deal with the basic physicochemical phenomena which underlie the application of the complement fixation test and the flocculation phenomenon to the serodiagnosis of syphilis. Each part ends with a description of acceptable techniques for performing the respective types of test. In addition part II contains a searching critical examination of the methods for choice of an optimum flocculation test, with a succinct summary. Part III is devoted to methods of examination of the cerebrospinal fluid and in

part IV the author deals briefly with a variety of miscellaneous laboratory tests for syphilis. Parts V and VI are given to discussion of the clinical evaluation of serologic reports both from the point of view of the theoretical considerations involved and with regard to the statistical results of the competitive serologic conferences.

This routine description of the contents of Dr Eagle's monograph gives no idea of its true worth. It is unique in that in a single volume it deals both with the laboratory and with the clinical aspects of the serodiagnosis of syphilis. This may seem of small importance until one remembers that there are few clinical syphilologists who are competent serologists and that there are almost no avowed serologists who are competent clinicians. Then the consummate value of this monograph becomes apparent. Here for the clinician are simple methods for judging the reliability of the serologic laboratory on which he depends and authoritative advice on the interpretation of the reports of serologic tests for syphilis. The practicing serologist will find quite as much of value. The chapters on technic are based on the personal experiences of the author and are presented without bias. There is a full index.

Eyestrain and Convergence By N A Stutterheim MD Part Time Ophthalmic Surgeon to the Johannesburg School Clinic Transvaal Education Department Cloth Price 7s 6d Pp 89 with 2 illustrations London H K Lewis & Co Ltd 1937

For a number of years the author, through the pages of the *British Journal of Ophthalmology*, has reported studies on the ocular musculature in their relation to the position of the eyes and as to convergence. The present volume is aimed to provide a method of treatment for the common complaint of eyestrain. This method is not to be thought of as an additional procedure to the procedures already available but is initiated as a long overdue reform. The author states that the principles of this new method are based on physiology and leaves it to his medical colleagues to decide whether it is worth. The need for this new idea is based on the premise that, in spite of the complaint of eyestrain, modern methods of refraction and muscle therapy yet leave many persons, more especially those seen in private practice, with no relief from their symptoms of eyestrain. Evidently this is true in South Africa. The new concept deals with the kinetic factor of binocular vision. The static factors (so called) of errors of refraction and muscular balance are rejected as far as their traditional concepts are concerned. The soundness of this new kinetic binocular consideration and the principle of kinetic treatment are established by the undeniable and consistently good results in more than a thousand cases. The importance of convergence is brought forward by a discussion of its center in the midbrain and a citation of its prominence in the animal world. Stutterheim believes that the convergence is based rather on a tensor system than on contraction and inhibition of antagonistic muscles. This theory is exemplified by the good convergence when the external rectus is practically absent and by some of Sherrington's experiments. The primary position is conceded to be one in which the two eyes are slightly divergent. The author shows that there is a difference in voluntary adduction of the eyes and kinetic convergence. The term "asthenovergence" is used to denote the difficulty found in persons complaining of eyestrain. The method of testing for this defect is as follows. "In the examination of cases of eyestrain, insufficiency of convergence which I have called asthenovergence, is regularly found. The person is tested for power range of convergence while sitting opposite a black cloth 4 feet square at a distance of 5 or 6 meters. In the center of the cloth an oblong strip of white cardboard 75 by 10 cm is fixed and serves as the object of vision. It is placed in the vertical position in the tests for horizontal convergence and in the horizontal position in the tests for vertical convergence. The tested person's head is supported by a rest for the chin and one for the forehead. Into the forehead rest a trial frame is fixed for holding the single prisms. The test is done by successively placing prisms of increasing strength (but not re-ol my prisms) in front of the eyes until the images no longer merge but remain apart. The difference between the separate prisms I use for the tests on horizontal convergence is 1 degree of prism, for the tests

on vertical convergence it is $\frac{1}{4}$ degree of prism. When the images no longer merge, the preceding number of prisms is taken as the result of the test."

Elschnig has established the normal range of convergence as 50 degrees of prism. The symptoms of eyestrain are multiple. In many persons amblyopia, visual field contractions or migraine may be some of the symptoms, and these are relieved by treatment of the asthenovergence. The test and treatment advised are the use of a battery of prisms increasing by diopters for horizontal deviations and by 0.25 diopter for the vertical. Many sittings are often necessary to increase convergence to a degree at which symptoms of eyestrain are relieved. The results obtained in 100 cases of eyestrain are noted. Increase of convergence from 7 to 10 degrees up to 70 or 80 degrees is not unusual. An adequate number of typical cases are discussed in detail. The value of the method and the author's enthusiastic results may be gaged when others have had the opportunity to try the procedure. The physiologic cure of such conditions as amblyopia, migraine and contracted visual fields must be regarded with a degree of question. Nineteen references in the literature are given, and an adequate index closes the volume.

Income and Expense Record of Doctor
for the year from 1933 to 1934
Cloth Price \$3 Pp 52 Michigan City Indiana Hill Publishing Company 1932

This comprises printed forms on which to keep the monthly accounts of cash payments. There is a sufficient number of these forms, it is assumed, to last for one year, there are also other forms for monthly accounts of cash receipts and earnings, with space for summarizing the miscellaneous receipts of the month, and the amount of cash services and the amount received on account. Accompanying the bound set of forms are pads of unbound and simpler printed forms on which to record daily cash receipts and earnings and at the same time show whether any new business was cash or charge and whether it was a miscellaneous item. These forms were prepared especially for physicians who do not desire a more complicated system of bookkeeping. It enables the physician to determine from day to day and from month to month the net result of his practice and other interests. There are instructions about how to make the entries. The requirements of the federal income tax laws have been kept in mind, so that the preparation of the income tax return will be made simpler.

Diathermy Including Diathermotherapy and Other Forms of Medical and Surgical Electrothermic Treatment By Elin P. Cumberbatch M. A. B. M. D. M. R. C. Medical Officer in Charge of Electrical Department and Lecturer on Medical Electricity St. Bartholomew's Hospital London. With nine collaborators. Third edition. Cloth Price \$6 Pp 576 with 170 illustrations. Baltimore: William Wood & Company 1937.

Since the publication of the second edition of Cumberbatch's *Diathermy* in 1928, considerable advance has been made in the medical and surgical uses of high frequency currents and there has been added the newer form of electrothermic treatment recognized in the United States under the name of short wave diathermy. To cover this progress Cumberbatch has added 244 pages to his volume and has enlisted the aid of nine collaborators.

There are three main parts of the volume, the first including history and the physical and electrotechnical principles, the second medical electrothermic methods and the third surgical electrothermic methods. In the first part a chapter on physical principles by the physicist H. J. Taylor contains besides much pertinent information about the newer forms of high frequency currents also a multitude of formulas and equations of possible interest only to physicists. In the second part chapters of special contributors deal with diathermy in gynecology and in chronic arthritis, in diseases of the cardiovascular system in treatment of dementia paralytica and in ophthalmology. There is a critical and fairly exhaustive chapter on the physical and clinical aspects of short wave diathermy under the admittedly inexact heading of short wave treatment. According to Cumberbatch's comparative studies, "in disease that is not deeply situated there appears to be little difference between the results of diathermic treatment and that obtained by short

waves, although the technic practiced renders the latter more comfortable for the patient and much easier for the practitioner. A special chapter is devoted to the subject of inductothermy. In the third part of the volume, comprising almost 200 pages there are chapters by collaborators on electrosection and on electrosurgery in malignant disease of the upper air passages, for the destruction of the tonsils, for prostatic obstruction and in ophthalmology, and chapters by the author covering the other fields.

The volume is well illustrated, is written in a fluent style and contains many references to American clinicians and methods. It is a valuable contribution of a leading English authority and is of practical interest to both beginners and experts in the field of medical electricity.

Hilfsbuch für raum und aussenklimate Messungen mit besonderer Berücksichtigung des Katathermometers Von Franz Bradtke und Walther Liese. Paper Price 7.50 marks Pp 100 with 30 illustrations. Berlin: Julius Springer 1937.

This volume is designed as an aid to the practicing hygienist and to heating and ventilating engineers, in addition to the answers given to medicometeorological and bioclimatic questions. In addition to the main considerations of heat, of various kinds and degrees, as related to the comfort of the individual while indoors, some consideration is given to outside climatic conditions. The main value of the book lies in two directions. First, a clear though brief outline of the biophysical influences affecting bodily comfort. Such factors as temperature sensation, production of heat, chemical and physical heat regulation, heat losses, influence of moving air, moist air, radiant heat, pigmentation, ionized air, and dust in air are considered. Second, and most comprehensive, is the discussion of the various factors in relation to the means for attaining practical measurement. One section is devoted to such matters as wet and dry thermometers, psychrometry, equivalent temperature, effective temperature, resultant temperature and radiant heat, with a concomitant discussion of such instruments as the psychrometer, the protimeter, the eupatheoscope, the globe thermometer, the homotherm and the weather "frigorimeter." The differences in meaning between the various terms is aptly illustrated by the elucidation of the uses of the various instruments. Special emphasis is laid on the working and use of the katathermometer. The discussion on this subject is valuable to any one interested in measurements by means of the katathermometer. The theoretical aspects of the instrument are carefully considered, though the practical use of this section would be of more interest to one interested in the physical sciences. However, the actual measurements and methods of use in various situations are covered in detail, so that a variety of interest is engaged. Another good point is the listing of the minimal equipment needed for determining room and outside air conditions. The voluminous detail should again be noted, as such information is not usually given clearly enough to be of value to those just entering into this field. In its entirety this book should prove to be a valuable aid to those who have any interest in the subject of air conditioning and the effects of surrounding influences on the human body.

The Physician's Business: Practical and Economic Aspects of Medicine By George D. Wolf, M.D., Attending Otolaryngologist, Sydenham Hospital, New York City. Foreword by Harold Rypins, A.B., M.D., F.A.C.P. Cloth Price \$5 Pp 384 with 57 illustrations. Philadelphia: New York, Montreal & London: J. B. Lippincott Company 1937.

The author discusses many of the practical business matters of medical practice which are important especially to young physicians. Obviously the physician gives first consideration to the care of his patients, often he finds little time remaining to keep the business side of the practice in good order. The author aims to counsel and to place at the disposal of physicians much practical information of this kind. He advises concerning the selection of a location and the equipment of an office. He discusses such ethical questions as obligations to patients, relations to his colleagues and to consultants and hospital and dispensary affiliation. He reproduces actual reports of consultants to family physicians concerning examinations that have been made of patients. He points out the advantage to physicians of becoming affiliated with their county medical society.

and the American Medical Association. He gives advice about the preparation of medical papers, public addresses and radio talks. The chapter on "The Doctor and His Patient" includes a discussion of medical fees and of the daily records that a physician should keep. In this chapter is a section entitled "Instructions to Patients." The author believes one should give written, rather than oral, instructions to patients whenever practicable. Among these typewritten instructions are some entitled "Care of the Baby," "Anticonstipation Diet," "Obesity Diet" and "Scabies," under which he has seven points instructing the patient how to get rid of this malady. Other typewritten instructions to patients include setting up exercises illustrated by simple drawings, massage, how to prepare a turpentine stupe, flaxseed poultice and mustard baths. There are instructions on how to irrigate the nose, throat, ear and eye, how to give proctocolysis and hypodermic injections, how to set up trays for various operations, what to include in a blood transfusion set and an obstetric case and what equipment is necessary to perform a hemorrhoidectomy and a circumcision. There is a chapter on forensic medicine and another on the income tax, showing how to keep records which make easier the preparation of the income tax return. There is a brief chapter on the current trends in medical practice and a discussion of economic evils of the present day. The book contains much information that will help especially young physicians.

Beitrage zur Entwicklung der Strukturen und Kreuzungen im Zentralnervensystem. Von Professor Dr. Dolken. Boards. Price 5.80 marks. Pp. 69 with 51 illustrations. Leipzig: Georg Thieme, 1937.

The author discusses briefly the various decussations and commissures of the central nervous system from the standpoint of embryologic development, physiology and anatomic structure. The eye and the optic nerve are considered, as by Cajal and others, to be the primary factor which is the basis of other decussations and commissures of the central nervous system. Commissures are present not only as gross elements of fiber tract structure but also in the histologic elements as networks, commissures and decussations within individual nerve cells and also of individual nerve fibers. The phylogenic relationship between primitive nerve network in lower animals with the network in parts of the higher vertebrates is discussed briefly. The latter half of the monograph is devoted largely to the embryologic development of the nuclei and tracts of the cranial nerves. The monograph is well illustrated and has a full bibliography, which, however, is not so extensive as to include too many minutiae.

Practical Neuroanatomy. A Textbook and Guide for the Study of the Form and Structure of the Nervous System. Adapted to the Needs of the Student and Practising Physician. By J. H. Globus, B.S., M.D., Associate Professor of Neuroanatomy, New York University. Cloth. Price \$6. Pp. 387 with 148 illustrations. Baltimore: William Wood & Company, 1937.

After years of teaching his subject to medical students, the author, a well known neuropathologist and neuro anatomist, has incorporated his material in this book. He explains clearly and adequately the difficult subject in its broad outlines and the book has many beautiful illustrations. The anatomic explanations are unusually clear and understandable. In a separate section, details of neuropathologic staining technics are briefly described. At the end of the book outlines for student drawings are printed on perforated pages so that they can be detached. These are especially useful for medical students. The work is highly recommended for its purpose in teaching students neuro anatomy.

Skin Diseases in General Practice. Their Recognition and Treatment. By H. Haldin Davis, D.M., M.A., F.R.C.P., Consulting Dermatologist to the Royal Free Hospital, London. Third edition. Cloth. Price \$6.25. Pp. 400 with 97 illustrations. New York & London: Oxford University Press, 1937.

This concise and practical treatise makes no pretense at being a complete textbook of dermatology and within the limits set by its author it fulfils its purpose. The arrangement of the diseases of the skin according to their topographic distribution follows the plan of Sabouraud's *Dermatologie topographique* and is of value for ready reference. There is of course some unavoidable overlapping in the consideration of those diseases which may appear anywhere on the body. Due emphasis is

given the recent therapeutic advances, particularly the use of gold compounds in erythematous lupus and the modern methods of applying radium in cutaneous cancer. X-ray dosage is still expressed in "pastille" doses. There may be a valid objection to such statements as "In the treatment of acne vulgaris a dose should be given a little short of a pastille dose." Most American dermatologists advise smaller doses at weekly intervals. The illustrations are numerous and well selected and those in colors are particularly good. The format of the book is excellent and the practitioner will find the diagnostic and therapeutic side of the subject adequately covered in spite of the omission of histopathology and of the rarer skin diseases.

Modern Treatment in General Practice. Volume III. Edited by Cecil P. G. Wakeley, D.Sc., F.R.C.S., F.R.S.E., Senior Surgeon, King's College Hospital, London. Cloth. Price \$4. Pp. 436 with 70 illustrations. Baltimore: William Wood & Company, 1937.

This is the third volume, entitled "Modern Treatment in General Practice," which has been assembled by the editorial staff of the *Medical Press and Circular* from articles published in that periodical by well known men in the British Isles. There are fifty-one articles in this volume and there seems to be no special connection between them except that all emphasize diagnosis and treatment. The first one, by Gordon-Taylor, is entitled "The Surgical Treatment of Cancer of the Stomach." The fortieth article, for example, is by James Maxwell, entitled "Treatment of Asthma," and the last article is by Leonard Williams, entitled "Dietetic Essentials in General Practice." Those interested will find in the front of the volume a list of the articles and the authors of both volume I and volume II.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Compensation of Physicians. Value of Services not Dependent on Saving Patient's Life.—A physician operated on Charles Smith at the University of California Hospital, in San Francisco. The patient died and the physician assigned his claim for fees to one Baird, who brought suit against Smith's widow in the municipal court of San Francisco. That court granted a motion by the widow to transfer the cause to her home county, Butte. At the trial there the plaintiff moved that the cause be retransferred to San Francisco for the convenience of witnesses. Affidavits were presented tending to show that a trial in San Francisco would accommodate fifteen named witnesses, all of whom were physicians, or employees of the hospital previously referred to, and none of whom could attend a trial in Butte County without great loss and inconvenience to themselves and to the hospital. The affidavits further stated that all witnesses were familiar with the facts and would testify as to the value of the services performed. The defendant filed two counter affidavits based on information and belief. One affidavit alleged that it would be necessary to call as witnesses on behalf of the defendant four physicians of Butte County who would testify that the patient's ailment was necessarily fatal, that the performance of the operation in question was useless and that therefore the services rendered were not worth the sum demanded. The other affidavit merely alleged that each and every witness mentioned in the plaintiff's affidavits was not a necessary or proper witness and would not be qualified to testify as to the value of the services. The superior court of Butte County denied the plaintiff's motion for retransfer to San Francisco and the plaintiff appealed to the district court of appeal, third district, California.

The trial court abused its discretion in denying the application, said the appellate court. The convenience of witnesses and the interest of justice required a change of venue to San Francisco. Furthermore, the affidavits presented by the defendant failed to indicate any competent evidence of material facts to be testified to by any physician in Butte County who would be inconvenienced by retaining the trial in that county. One affidavit

merely named four physicians who would testify as to the character and value of the services. The fact that these physicians would testify that the operation was useless and ineffectual to save the life of the patient was not material to the issue of the case. Ordinarily the value of a physician's service is not dependent on saving the life of a patient. The skill of the greatest surgeons in the world is sometimes futile. The court also believed that the counter affidavits of the defendant were worthless or of little value because they were based on information and belief and stated mere conclusions without stating facts on which the conclusions were based.

For the reasons stated the district court of appeal directed the superior court of Butte County to grant the motion for change of venue to San Francisco—*Band v Smith (Calif)*, 68 P (2d) 979

Workmen's Compensation Acts Physician Not Authorized to Treat Compensation Cases May Not Collect Fee—The workmen's compensation law of New York was amended in 1935 so as to provide that medical care under the act may be rendered only by physicians authorized so to do by the state industrial commissioner. The plaintiff, a licensed physician, at the request of the defendant an employer rendered medical care to a workman injured in the course of his employment. Subsequently he sued the employer for the value of his services but failed to allege that he was authorized by the industrial commissioner to render medical care. The trial court for that reason dismissed his suit. The supreme court of New York, appellate division, affirmed the dismissal (*Szold v Outlet Embroidery Supply Co Inc* 248 App Div 865, 291 N Y S 395, abstracted, THE JOURNAL, May 15, 1937, p 1743), and he appealed to the Court of Appeals of New York.

It was not unreasonable, said the court for the state to declare a man to be a competent physician by licensing him to practice medicine and then to impose the additional requirement of a special authorization if the patient happens to be a workman suffering from accidental injuries, arising out of and in the course of his employment. The presumption is that the legislature inquired and found the need of special training or fitness for the treatment of compensable industrial injury and occupational disease. The act in providing that no physician may be authorized by the commissioner to treat workmen's compensation cases unless recommended by a medical society or by a board composed of physicians did not deny the plaintiff due process of law nor unlawfully delegate legislative power to nongovernmental agencies. The provisions in the act designed to control the amounts to be awarded for medical services, said the court, constituted a legitimate exercise of the police power of the state. The medical care which the employer must furnish is part of the statutory compensation of the workman. It may well have been conceived that the minimum fee requirement would effectively put a stop to unwholesome competition for opportunity to treat employees and that it would also attract the more skilful and experienced physicians into the field. Power exists, said the court, to assure full delivery of workmen's compensation to be awarded in money. The power to say that compensation in the form of medical care shall be adequate in quality is not essentially different.

To the contention that the 1935 amendments were unconstitutional in that they made voluntary medical societies new departments of the state government and that compulsory arbitration of the value of medical services contravened the constitutional right of jury trial, the court referred to the following provisions of the state constitution authorizing the enactment of a workmen's compensation act: "Nothing contained in this Constitution shall be construed to limit the power of the Legislature to enact laws for the protection of the lives, health, or safety of employees or for the payment by employers

either directly or through a State or other system of insurance or otherwise, of compensation for injuries to employees or for the adjustment, determination and settlement with or without trial by jury, of issues which may arise under such legislation.

The judgment of the lower court against the plaintiff was affirmed—*Szold v Outlet Embroidery Supply Co Inc (N Y)*, 3 N Y (2d) 878

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Cardiac Complications of Hemorrhagic Nephritis—Rubin and Rapoport investigated the status of the heart of fifty-five patients with acute hemorrhagic nephritis. Fourteen children (two deaths from acute cardiac failure) with varying degrees of cardiac involvement during the acute stage of their illness have been encountered. Further analysis of these fifty-five patients revealed rather unexpectedly that cardiac involvement was the most frequent accompanying complication of acute hemorrhagic nephritis. The clinical evidences of cardiac involvement and failure observed in the cases were: (1) dyspnea, tachypnea and cough, (2) cardiac enlargement, demonstrable both by physical examination and in teleroentgenograms, (3) muffled heart tones, (4) rapid heart rate, (5) murmurs, usually a mitral systolic murmur, (6) gallop rhythm, (7) enlargement and tenderness of the liver, (8) engorgement of the venous system, (9) pulmonary edema, (10) peripheral edema and (11) electrocardiographic changes indicative of varying degrees of myocardial damage. During the acute phase of the disease two factors are operative which may affect the heart adversely: myocardial damage and increased peripheral vascular resistance (hypertension). With regard to myocardial damage, it is possible that the same infective agent responsible for the acute nephritis damages the heart. Hypertension (which is evidence of increased peripheral resistance brought about by vasospasm) is the agent immediately responsible for the impairment of cardiac function. Hypertension has been present in all the patients with acute hemorrhagic nephritis exhibiting signs of cardiac insufficiency. In those cases in which the heart is primarily involved by the disease it is likely to fail under the added load of a sudden increase in peripheral resistance. Whether or not cardiac failure results is dependent on the extent of the myocardial damage and the degree of hypertension. The only deaths in the entire group of fifty-five nephritic patients were due to cardiac failure. The authors administered magnesium sulfate by intramuscular injection using a dose of 0.2 cc of a 50 per cent solution per kilogram of body weight. The effects of a single dose are usually prompt. Fluids should be restricted in cases of acute hemorrhagic nephritis with hypertension, for there is danger of producing a further elevation of blood pressure and precipitating a cardiac catastrophe. Supportive measures for the heart were instituted in addition to the use of magnesium sulfate and the limitation of fluid intake. After administration of a complete digitalizing dose it was usually found unnecessary to continue with a maintenance dose. In cases in which there was cardiac involvement of any degree sedation (morphine) was valuable. The ultimate prognosis as

regards the heart itself is good, as only one of the twelve surviving patients who had cardiac involvement shows residual cardiac damage.

Cryptorchidism Treated with Gonadotropic Principle

—From a study of seventy-one boys with ninety-one undescended testicles who were given injections of the gonadotropic principle of the urine of pregnant women and the gonadotropic principle of the anterior lobe of the pituitary gland, Bigler and his co-workers find that these extracts produce changes in the external genitalia of some patients but not in all. The changes when present are manifested by flushing of the genitalia, enlargement of the testicles and penis or descent of the testicles. In the patients treated with the gonadotropic principle of the urine of pregnant women 48 per cent of the undescended testicles completely descended into the scrotum by the end of treatment but only 45 per cent remained descended. If the partially descended testicles are included, 61 per cent can be considered benefited. In the patients treated with the gonadotropic principle of the anterior lobe of the pituitary gland 25 per cent of the testicles completely descended into the scrotum but only 18 per cent remained descended. Including those in whom the testicles partially descended, 35 per cent were benefited. When both gonadotropic extracts were used in treating the patient 40 per cent of the cryptorchid testicles showed complete descent but only 25 per cent of the testicles remained in the scrotum, 55 per cent were benefited. When descent of the testicle occurs, it usually begins to take place before 4,000 rat units of the gonadotropic principle has been administered. Treatment seems to be about equally successful at any age after the first year, but it seems better not to begin treatment until after the seventh year of life. In a control series of fourteen untreated and inadequately treated patients (seventeen undescended testicles) descent of the testicles did not occur. Both extracts often caused enlargement of small testicles but never permanent enlargement of normal testicles. Both extracts produced enlargement of a normal-sized penis in eight boys. Reactions both general and local may occur during treatment. Treatment had no effect on weight or height or on body build, even when hypoplasia of the genitalia was present, with a feminine type of body build. If improvement does not occur by the time about 4,000 rat units of the gonadotropic factor of the urine of pregnant women has been administered, operation may be considered.

Tissues After Injection of Colloidal Thorium Dioxide

—Later and Whitmore performed necropsies on sixty-four patients at intervals of a few days to three years after the injection of an average dose of 75 cc of colloidal thorium dioxide for the purpose of making hepatosplenograms. In no case was there any evidence of injury to the tissues or cellular

reaction that could be ascribed to the presence of the thorium dioxide. A subcutaneous nodule was excised from the arm of a patient four years and five months after the injection of colloidal thorium dioxide accidentally into the subcutaneous tissues. The thorium dioxide was walled off by dense hyaline connective tissue, the nodule resembled the kind of nodule found in the lungs in nodular silicosis. Nowhere was there any evidence of injury to the tissues or cellular reaction other than the primary reaction resulting in the walling off of the thorium dioxide.

Congo Red Test for Amyloidosis—In evaluating the congo red test in the diagnosis of amyloidosis, Lipstein made an analysis of 125 necropsies on tuberculous subjects in whom a congo red test had been performed. Amyloidosis was diagnosed in the usual manner, that is, the use of iodine grossly and congo red or methyl violet staining for microscopic sections. In all these cases tuberculosis with its attendant complications was the predominant picture and the patients ranged in age from 2 to 72 years. At necropsy, amyloidosis was present in thirty-four. In twenty-nine of these cases the percentage of absorption was 90 per cent or higher, with complete absorption of the dye in twenty-four. There were five cases recorded in the amyloid group with less than 90 per cent of absorption of the dye. Postmortem examination in four of these cases revealed minimal or moderate amyloid changes and the spleen was the only parenchymatous organ involved grossly. A possible explanation for the low absorption values in these instances is that there were not sufficient amyloid deposits to absorb the dye. In the ninety-one cases in which no amyloidosis was present the percentage of congo red absorption in eighty-seven of the cases varied from 10 to 75. In the remaining four cases there were percentage values of 100, 95, 90 and 80, despite the absence of evidence of amyloid at necropsy. The study confirms the observation that, although amyloid changes are infrequent postmortem observations even in large general hospitals, the incidence rises sharply in tuberculosis institutions. In the present series amyloidosis was present in 27.2 per cent of the cases. In a statistical survey of approximately 1,000 necropsies at the hospital, the incidence was found to be 20 per cent.

Vitamin C in Alcoholism—The Wortises and Marsh determined the reduced ascorbic acid content in the blood and spinal fluid in normal persons and in 103 chronic alcoholic patients. In two patients the five hour urinary excretion test (Wright) was done. The studies indicate that in chronic alcoholism without peripheral neuritis or psychosis there is a tendency for a low normal vitamin C content of the blood and spinal fluid, whereas alcoholic patients with peripheral neuritis or the various forms of alcoholic psychosis tend to have a subnormal vitamin C content of the blood and spinal fluid. The results seem to emphasize the nutritional factor in the production of nervous and mental changes in chronic alcohol addicts. It is suggested that vitamin C may have a role in the metabolism of the nervous tissue.

Incidence of Poliocidal Serums—Hudson and Lennette present data on the incidence of poliomyelitis in various parts of the world, as determined by the presence in human serum of antibodies capable of neutralizing the specific virus. These studies were originally undertaken in the attempt to find regions in which this disease does not exist and in which possibly this type of antibody was not to be found. Those areas were selected in which epidemics of poliomyelitis occur at least infrequently, tropical to subtemperate zones. Poliomyelitis does not occur frequently in epidemic proportions in the tropics, although instances are on record. The survey increases the conception of the world-wide distribution of this disease, both because of the incidence of neutralizing serum and because of reports of sporadic cases in regions not otherwise heard from. The existence of these sporadic cases emphasizes the infrequency of poliomyelitis epidemics and, since the authors have examined chiefly tropical regions, their data lend support to the idea that the tropical conditions contribute some factor to the host-parasite relationship that allows for a common existence of the virus, generalized immunization, occasional sporadic cases and infrequent epidemics. Most of the tests were done by a qualitative method, the MV strain of virus being mixed with undiluted serum. Under the conditions of experimentation the poliocidal antibodies were apparently the same in the different serums, and the incidence of positive specimens was similar in the areas examined. As the same virus was neutralized by the various serums in the authors' experiments and with the interpretation that the so-called neutralization test is a specific antigen-antibody reaction, the data presented indicate that the virus in the widely scattered regions sampled is antigenically identical. Seven of nine adults of Thursday Island, Australia, and ten of twelve adults of Formosa, Brazil, possessed the neutralizing property. In the former place sporadic cases of poliomyelitis occur, and deaths from the disease have been reported from scattered parts of Brazil.

Thoracoplasty with Lung Mobilization—Overholt discusses the results of the 763 thoracoplasties performed on 570 patients during the five years that the department of thoracic surgery has been established in the Lahey Clinic. During the first half of this period selective thoracoplasty was used and during the latter half thoracoplasty with lung mobilization.

The group represents a consecutive series of patients operated on by the same surgical team. The number of seriously ill patients accepted for thoracoplasty has been increased, yet the risk of operation has steadily declined. Of those in the poor risk group, sixty had bilateral cavitation. Of the 206 patients in the "good chronic" group, 89.5 per cent were definitely benefited by the procedure, 51 per cent are already back at work and 25 per cent are in various sanatoriums with their disease quiescent or arrested. In the poor risk group 24 per cent are working and the condition of 26 per cent is quiescent or arrested. It was found that 69 per cent were benefited by operation. In the entire series 121 patients were completely rehabilitated. The possibilities are good that eventually the condition of 248 (80 per cent) of the 307 patients whose treatment has been completed will be classified as apparently arrested and that they will be able to carry out varying degrees of activity. The results suggest that thoracoplasty is the most valuable of all permanent collapse procedures. Selective yet adequate collapse of the diseased lung and conservation of the uninvolved lung should be the ideal in permanent collapse therapy. The extent of the decostalization can be reduced by mobilization of the upper lobe at the time of the first-stage operation. A delay between stages is an important factor in planning the most conservative operation.

Short-Interval Operations for Severe Hyperthyroidism.—After trial and observation of intervals varying from one day to two weeks, McGraw is convinced that the optimal period for "short-interval" stage thyroidectomies in severely toxic goiter patients is from seven to ten days between operations. A single period of hospitalization of a month or less by shortening the interval between operations to a week or ten days is often necessary in certain goiter patients owing to their financial or educational status. If the patient's condition permits, unilateral lobectomy is the first stage operation of choice. At the first stage the entire isthmus and pyramidal lobe, if present, should also be removed—even at the expense of dealing first with the smaller of two diffusely hyperplastic lobes. At the conclusion of the first stage it is preferable to omit subcutaneous suture of the skin flaps, to use cutaneous clips rather than through and through sutures, and to avoid draining the wound. Before proceeding with the second operation, one should allow the slightest imperfection in wound healing to clear up completely. The wound should be reopened gently and slowly so that as little subcutaneous bleeding as possible will be caused and that any area in the wound suggestive of infection may be detected before the wound is widely opened. At the end of the second operation the wound should again be closed without subcutaneous skin sutures and again preferably

with clips. The final scars of these two stage operations have been surprisingly excellent. The matter of drainage after the second operation must be left to the surgeon's judgment in the individual case. No drains should be left in place more than twenty-four hours.

Blood Loss in Neurosurgical Operations.—White and his colleagues estimated the volumes of blood lost during operation by three different surgeons and found that in simple craniotomies, when nothing more than an exploration and cerebral biopsy was carried out, the average loss amounted to between 500 and 900 cc. In patients with relatively avascular tumors the loss of blood rose to between 600 and 1,200 cc. In three patients with large meningiomas the hemorrhage exceeded 2,000 cc. In five laminectomies the loss of blood varied from 334 to 1,263 cc. A hemorrhage of more than a liter may seem excessive, but with an epidural abscess or a vascular tumor, or in a hypertensive patient, both the muscles and the bony lamina may bleed profusely. In a patient with a hemangioma and compression of the spinal cord, the attempt to expose the tumor had to be given up after two trials owing to severe hemorrhage. On the other hand, in two patients on whom cervicothoracic ganglionectomy and section of the fifth cranial nerve root were carried out, bleeding amounted to only 107 and 86 cc. Excessive bleeding which occurs in the usual neurosurgical operation is due to certain regional conditions. A wide infiltration of the scalp with a 1 per cent procaine epinephrine solution diminishes bleeding. The authors' preference is to supplement this with basal tribrom ethanol in amylene hydrate, as this drug produces a moderate fall in blood pressure and thereby diminishes hemorrhage from the cerebral vessels. Basal narcosis contributes to the comfort of the patient and reduces nervousness and restlessness. Administration of the general anesthetics ether and nitrous oxide should be avoided whenever possible because they increase bleeding. Nitrous oxide-oxygen anesthesia also produces increased bleeding because it so frequently causes partial asphyxia. When a general anesthetic must be used, a preliminary infiltration of the scalp with 0.5 per cent procaine-epinephrine solution is of value not only as a hemostatic agent but also because a lighter level of anesthesia can be employed. When it is estimated that a hemorrhage of a liter or more has occurred, a transfusion is given before the patient is sent to the ward. After hemorrhages exceeding 1,200 to 1,500 cc, or whenever the blood pressure remains at a critically low level, multiple transfusions are given. This can be carried out in the ward if the intravenous infusion has been kept running. The total fluid intake on the day of operation should rarely exceed 2,000 cc and should be given slowly over a period of from five to eight hours.

Comedo Carcinoma of the Breast.—Lewis and Geschickter state that comedo carcinoma usually presents two rather characteristic pictures: diffuse and localized. Diffuse comedo carcinomas present some of the clinical features peculiar to intracanalicular myxoma. It is a slowly growing tumor which involves the greater part of the affected breast, and an isolated tumor cannot be palpated in the enlargement. Despite the size of the growth there are frequently no palpable lymph nodes. Small elevations in the skin may be found which are caused by

the protrusion of the epithelial plugs within the ducts, and not infrequently a discharge from the nipple is noted. In the localized form the tumor is small, measuring from 1 to 3 cm in diameter. It is usually situated at the margin of the areola just beneath the skin and is freely movable. The axillary nodes, as a rule, are not involved, and not infrequently a yellowish or watery discharge from the nipple is noted. The affected breast is slightly larger than the uninvolved breast. The tumor differs from the intracystic papilloma and the blue dome cyst in that it is relatively harder and more irregular. The age incidence of comedo carcinoma corresponds to the age incidence of other forms of carcinoma of the breast. The location of the comedo carcinoma suggests an origin in the larger ducts. Retraction or fixation of the nipple occurs often, and occasionally the patient complains of burning and itching of the nipple, a symptom more common in Paget's disease. The tumor is usually located near the skin, and atrophy of the overlying fat and dimpling of the skin occur. The tumor remains movable. Even when the growth is larger than a large grapefruit and involves almost the entire breast, there will be no fixation to the wall of the chest. Several tumors may be found in the same breast. Of all the forms of carcinoma of the breast, comedo carcinoma offers the most favorable prognosis. There were 85 per cent of five year cures. The majority of the patients living more than five years after complete operation have remained well for ten years or more.

Etiology of Mesenteric Lymphadenitis—Ireland's report is based on a series of twenty-two patients in whom mesenteric lymphadenitis was found at operation. Appendectomy was performed on all but two. Twenty-one of the twenty-two patients recovered, and one died of streptococcal peritonitis due to the rupture of a suppurative gland. Infections and toxins have probably been advocated as etiologic factors more than any other agents. That an actual infection of the glands themselves occurs in some patients is definitely proved. Attempts to find organisms in the glands removed at operation have usually been unsuccessful, indicating that a toxin may possibly be the underlying factor in many cases. However, it has been definitely excluded in some patients in whom organisms have been found. Conceptions of the port of entrance of the causative agent into the glands have differed. The appendices of nineteen of the patients in the present series were examined microscopically, and only eight showed any evidence of pathologic change. The appendix is a part of the large intestine and it is a well known fact that the mesenteric lymph glands are frequently not enlarged in cases of acute or of chronic appendicitis. It may be possible that a kinking, twisting or obliteration of the lumen of the appendix may be a factor in some cases. However, an anatomic condition of this character was found in the appendix in only two cases in the present series and consisted of a kinking of the organ. Of the twenty-two patients in the present series, twenty were traced and reexamined. These final examinations were made from sixty days to four years and 285 days after appendectomy. Sixteen of them had had no kind of abdominal distress simulating another attack of mesenteric lymphadenitis since operation, but four were found to have attacks much like those present before operation. The weight of evidence seems to be against those who believe that an infection from the appendix can be excluded as a causative factor in mesenteric lymphadenitis. The percentage of recoveries after appendectomy seems too high to be a mere coincidence. Brennemann suggested that bacteria may be transmitted from the throat by the blood stream or may be swallowed and produce localized inflammatory lesions in the intestine with secondary involvement of the lymph glands. Of the twenty-two patients, there were fifteen (68 per cent) who presented evidence of infection of the upper respiratory tract at the time of operation or just preceding it. It is reasonable to suppose that a higher percentage would have been found if such evidence had been carefully looked for in every instance. Distention, catarrhal inflammation, trauma, intestinal stasis, incompetence of the ileocecal valve with autoinfection of the ileum, regional ileitis, abrasions of the mucous membrane and lowered resistance of the surface epithelium of the intestine have been thought to be important in the production of mesenteric lymphadenitis. Allergy seemed certainly to be the causative factor in one

patient of the present series who had attacks of abdominal pain after appendectomy similar to those before operation. Epinephrine hydrochloride given hypodermically during the paroxysms of pain gave relief. Eggs, pineapples and blueberries were removed from the diet, and the attacks ceased immediately and had not recurred at the last examination, eleven months after these offending foods were eliminated. Careful studies were made of the two other patients who had attacks after appendectomy, but the cause was not found. Therefore it seems clear that there is no one etiologic factor that is responsible for the condition.

Sudden Death in Infancy—Nineteen of thirty cases of sudden death in infancy showed definite inflammatory lesion at necropsy, indicating, Goldbloom and Wiglesworth believe a fulminating bacterial infection. Four infants were asphyxiated from a mechanical cause (three from the aspiration of milk and one from a large hemangioma of the trachea). One child in addition to a healing pneumocele, had a most remarkable localized hypertrophy of the islands of Langerhans. Five of the remaining sixteen patients showed indefinite inflammatory lesions but taking into consideration the clinical and pathologic changes which were all similar it is possible that they all died of a fulminating infection. The cases were characterized by a vague preceding history, sudden death and at necropsy by interstitial pneumonia, petechial hemorrhages in the lung, thymus and pericardium and sometimes by a septic type of spleen. The sixth patient probably died of laryngeal spasm associated with tetani. The thymuses with two exceptions were not sufficiently enlarged to be abnormal. One of the children died from the aspiration of milk while the other showed evidence of a generalized infection. The weight of the thymus in the group of patients who died suddenly was the same as in those who died in twenty four hours from the

of definite clinical signs of infection. None of the classic features of the status lymphaticus syndrome were present. Sudden death has frequently occurred when the thymus was small. It is suggested that many cases of sudden death, although not all, are caused by fulminating infections possibly associated with immature immunity on the part of the infant. Postmortem examinations in cases of sudden death should be thorough before the easy diagnosis of status thymicolymphaticus is yielded to. When no pathologic lesion can be found, the pathologist must look to the biochemist or endocrinologist for help.

Edema of Menstruation—Thorn and his associates observed the fluctuation in the body weight of fifty normal women over a period of thirty-five days. This period represented one complete menstrual cycle. The ages of the subjects, nurses and dietitians, varied between 19 and 36 years. The subjects were weighed each morning immediately prior to breakfast. No attempt was made to control either the total fluid or food intake. In general, the food provided for all members of the group was similar. The onset and duration of menstruation were noted, as well as the occurrence of any unusual signs and symptoms such as headache, swelling of the abdomen, hands and feet, increased appetite and thirst. During the period of observation, the mean daily atmospheric temperature varied between 76.9 and 56.8 F. The relative humidity, measured at noon, varied between 82 and 19 per cent. Twenty-four of the subjects were observed to gain 1 Kg (2½ pounds) or more during the premenstrual period. In addition nine subjects gained weight during the premenstrual period but a subsequent loss occurred prior to the onset of menstruation. In many of the subjects the onset of menstruation was characterized by a rapid loss of weight. During the intermenstrual period thirty-eight subjects were observed to have a marked fluctuation (temporary gain) in weight (1 Kg or more) at or about the time of ovulation. Since the increase in body weight was noted from eight to fifteen days preceding menstruation, it is probable that ovulation occurred in many during the period of increase in weight. The increase and subsequent loss of weight that occurred during the intermenstrual period were not always followed by an increase in weight during the premenstrual period. Approximately two thirds of the subjects who gained weight during the premenstrual period noted swelling of the abdomen and increased appetite and thirst. The subjects in whom no significant increase in weight occurred also experienced the same signs and symptoms. Headache was frequently observed to occur immediately preceding or during menstruation. The increased intake of food and water as a result of an increased appetite and thirst contributed materially to the total

gain in body weight observed in some subjects during the premenstrual period. Balance studies demonstrated a retention of sodium, chloride and water during the intermenstrual as well as the premenstrual phase of the cycle. The onset of menstruation was associated with an increased renal excretion of sodium, chloride and water. The increase in the secretion of sex hormones and the increase in appetite and thirst appear to be contributing factors in the gain in body weight that occurs during the menstrual cycle.

Iron Metabolism in Experimental Anemia—Elvehjem and Hart and their associates claim that the dipyriddy test reacts only with the iron which is not bound in complex form (nonhematin iron) and that, since hematin iron is not available for hemoglobin production, the amount of iron in the food which can be utilized by the body is measured by this method. Hahn and Whipple offer evidence that such a premise is untenable. In experimental anemia in dogs due to blood loss the term "available iron" as determined by the dipyriddy test has no physiologic significance. Iron salts (100 per cent available by dipyriddy) given in optimal dose (560 mg in two weeks) will cause a net production of from 50 to 55 Gm of hemoglobin above the control base line in anemic dogs. This means that an iron salt which is rated as 100 per cent available by the dipyriddy test is only 35 per cent physiologically available. The term "available iron (dipyriddy)" simmers down to iron not in the form of hematin compounds. The absorption of this "available iron" is conditioned by a great variety of factors, many unknown at this time. Liver contains "available iron (dipyriddy)" but also organic factors influencing hemoglobin regeneration in anemia as liver ash contains only about 50 per cent the potency of the whole liver. Fractions of heart, liver, spleen and kidney may contain but little iron yet cause much regeneration of hemoglobin in anemic dogs.

- Effect of Beta Naphthylamine on Tissue Respiration F H Wiley, Wilmington, Del—p 92

Bladder Tumors from Beta-Naphthylamine—Hueper and his associates cite investigations that were undertaken in order to provide (through the experimental production of "aniline tumors" in animals) a sound foundation for the study of the various aspects of occupational neoplasms and to obtain information on any possible systemic effect of prolonged exposure to one of the suspected carcinogenic aromatic amines (beta-naphthylamine). Preneoplastic and neoplastic formations (papillomas, carcinomas) were obtained in thirteen of sixteen female dogs treated for a period of from twenty to twenty-six months with subcutaneous injections and oral feeding of commercial beta-naphthylamine. Periodic cystoscopic examinations combined with biopsies indicated that the pre-tumorous changes of the mucosa of the bladder are represented by blanched or red-brown elevated areas and small polypous, edematous protrusions. The neoplasms observed were pedunculated and sessile, benign and malignant papillomatous new growths and nodular, infiltrative carcinomas. Tumor multiplicity reaching, in several instances, the stage of generalized papillomatosis was a frequent phenomenon. The predominant localization of the tumors in the dependent parts of the bladder and the microscopic observations support strongly the urogenous origin of "aniline" tumors. Prolonged administration of relatively large doses of beta-naphthylamine produces blood destruction, degenerative changes in the tubular epithelium of the kidneys and in the parenchyma of the liver, which also contains adenomatoid, ill defined foci of regenerated liver cells. No detectable change was observed during the investigations in the pH of the blood or in its content of glutathione, dextrose, calcium, cholesterol and phospholipid phosphorus.

Bone Marrow Studies—The study of the bone marrow is recommended by Tuohy not as a routine but as an adjunct method especially in acute hematologic perversions. The statement often made that for the premortem diagnosis of "aleukemic leukemia" bone marrow smears are necessary must be reserved for those instances in which the circulating blood smear fails at any time to show qualitative leukocytic reversion. So far the author has not found such a case. The interpretation of the

leukopenias calls for the closest differential studies. Without expecting the direct study of the bone marrow to be entirely determinative, he regards its future as promising.

Anesthetic Actions of Esters of Mono Alkylated Amino Alcohols—Abramson and Goldberg determined the toxicity and anesthetic efficiency of monocaine and amylcaine on a number of different test animals. Monocaine was an effective compound in producing infiltration and conduction anesthesia. Although it was about one and one-half times as toxic as procaine, its anesthetic efficiency was many times greater. It produced block of the sciatic nerve in a nonanesthetized guinea pig in concentrations as low as 0.00016 per cent [$\frac{1}{625}$ per cent]. Amylcaine, although also capable of producing nerve block in low concentrations, appeared to be more efficient in effecting anesthesia when applied topically, as to the cornea of the rabbit's eye. The presence of erosions following the administration of this compound was less frequent than in the case of the other anesthetics.

Yeast Dermatoses and Contact Dermatitis—Ormsby states that a number of cutaneous and mucous membrane disorders formerly described as entities have been found to be due to yeast or yeastlike micro-organisms. Among the cutaneous disorders are erosio interdigitalis, perleche, waterbed dermatitis, paronychia, onychia and possibly seborrheic dermatitis. A mycotic dermatitis frequently occurs beneath the breasts in fleshy women, in the axillary spaces and in the anogenital region, and occasionally the process becomes generalized. Two or more or all of these disorders may coexist in a given patient. Oral thrush in infants responds well to swabbing with a 1 per cent solution of gentian violet, together with mild alkaline mouth washes. For superficial lesions of the mucous membranes of the mouth and vagina a 3 per cent solution of gentian violet is efficient, applied by swab twice daily. Alkaline mouth washes for the oral cavity and a douche containing a 1:2,000 solution of potassium permanganate for the vagina facilitate recovery. For the deeper lesions on the oral mucosa, surgical excision, x-rays and the internal use of potassium iodide may be necessary. Paronychia responds readily to the local application of a 5 per cent suspension of chrysarobin in chloroform. In the waterbed type, suspension of wet dressings together with the application of a soothing lotion, such as the lime water and zinc oxide lotion, together with a 10 per cent naftalan or 2 per cent ichthammol ointment, soon relieves the condition. In the intertriginous type occurring especially beneath the breasts and in the crotch, painting with a 3 per cent solution of gentian violet is efficient. When much inflammatory reaction is present, a preliminary treatment for several days may consist in soaking the parts twice daily with a hot solution of potassium permanganate in the strength of 1:2,000, dressing the parts in the interim with an ointment containing 10 per cent naftalan. In perleche, Finnerud found the local application of an 8 per cent solution of silver nitrate efficient. This application may be repeated at intervals of three or four days. Contact dermatitis, presumably produced by external irritants, is among the commonest of cutaneous disorders for which patients seek relief. These cases cover a broad field, beginning with the simple dermatitis venenata group and ending in that large group of cases which may be termed trade or professional dermatitis or eczema. The symptoms in all these cases are sufficiently similar to be classed together. It is important however, to be able to distinguish between them for the reason that dermatitis venenata is a comparatively simple malady, running its course in a short time and not recurring unless contact with the same irritant is repeated, whereas the other type may continue indefinitely through the development of new sensitizations. The number of substances capable of producing dermatitis by contact is endless. Contact dermatitis furnishes a large number of cases eligible for compensation under the industrial compensation act. The most important task in its treatment is discovery of the irritant and its removal. The treatment of the immediate attack consists of both local and internal applications and agents. An efficient method is the employment in the early stages of a lime water lotion several times during the day, alternated with the application of an oily cream. After two or three days when the eruption is less acute the same preparations may be

used during the day with an ointment containing naftalan or ichthammol over night. In some instances in which pyogenic infection has developed, a solution of aluminum subacetate or potassium permanganate may be necessary. Immunizing injections are of value in some cases and may be employed both for immunizing and for curative purposes. A method of treatment of all types of contact dermatitis which has been of great value is the use of sodium thiosulfate. This is given by intravenous injections, 0.5 Gm the first day and 1 Gm the second, third, fifth and seventh days. This drug has the ability of overcoming hypersensitiveness to a high degree. Cases that formerly extended over a period of several weeks commonly clear up in a week or ten days under its administration.

Radium Treatment of Leukemia—During 1935 and 1936 Fricke and Watkins treated, with radium, sixteen patients with atypical leukemias. Eight patients were diagnosed as having aleukemic phases of chronic myelogenous or lymphatic leukemia. One patient had a monocytic leukemia of the Naegeli type, and seven had types of reticulo endotheliosis. Once the diagnosis is established in these obscure cases with low leukocyte counts, radium is the treatment of choice in order to obtain satisfactory palliation. Roentgen therapy covers a larger portal and the effect of treatment is usually too sudden and drastic. The authors' best results have been obtained by the very cautious and well controlled use of radium. At a distance of 1 inch (2.5 cm) from the skin, 50 mg of radium sulfate (element), filtered through 2 mm of lead, was applied for a period of eight to twelve hours, depending on the leukocyte count, the size of the spleen and the general condition of the patient. Treatments varied from one to nine areas over the spleen in one treatment series and from eight to twelve hours of treatment per area, all carefully controlled by blood counts. Fifteen of the sixteen patients showed improvement in the condition of their blood and amelioration in their symptoms. The one exception was a man, aged 39, who suffered from an acute reticulo-endotheliosis following a severe attack of acute tonsillitis four weeks previously. Radium treatment was begun but was abandoned after twelve hours, as the patient was failing rapidly. He died two days later. Too little treatment was applied to have affected the disease one way or another.

Tuberculosis Among Medical Students and Physicians—Jennings points out that fourth year medical students have each spent two weeks as clinical clerks in Glen Lake Sanatorium since 1925. In 1929 they were first questioned with regard to tuberculin tests given them before they entered the sanatorium. Of the first eighty-seven students questioned 65 per cent had reacted positively when tested at the students' health service at the university to 1:1,000 dilution of old tuberculin. Beginning in the middle of November 1930 the next 184 students were tested on the day of entrance and 66.3 per cent were found to be positive to the intradermal test. The range of positive reactors to tuberculin varies for the years 1930 to 1936 inclusive from 52.5 to 67.8 per cent. The average of 62.04 per cent among the 851 fourth year medical students is less than that reported among fourth year medical students in the eastern part of the country. The number of positive reactors among the medical students of eastern schools increased in each year of the course until in their fourth year 98 per cent of them reacted positively. This steady increase is not necessarily confined to medical schools but is probably true of any

school at which the students' opportunities for infection must increase with continued residence among a large group of people. It is probable that the lower incidence among the University of Minnesota students as compared with that of the eastern schools lies in the fact that Minnesota's students, for the most part, come from communities less densely settled than do the students attending eastern schools. The possibility of tuberculous disease was taken into consideration from the first, and roentgenograms were made of the students' chests the day they started work at the sanatorium. The period here covered extends from 1920 to Sept 15, 1930. To the 670 in this group who had been here for training at some time during the ten years, questionnaires were sent early in 1932 in an attempt to ascertain the state of their health during the interval between receipt of this questionnaire and their sanatorium residence. Replies were received from 526. The replies disclosed that 267 of the normal group of 473 had considered themselves in good condition and had not troubled to have subsequent roentgenograms of their chests. Of the 206 who had had subsequent roentgenograms, 168 still had normal readings. Thirty others reported evidence of acute or chronic nontuberculous conditions variously diagnosed as bronchitis, bronchiectasis, emphysema and the like, but no evidence of adult tuberculosis. Ten per cent (fifty-three) of the students who came to the sanatorium showed deviations from the normal that might constitute possible evidence of tuberculosis when their chests were first examined. The answers to the questionnaire that was sent to these students from one to ten years after their period of instruction at the sanatorium showed that thirty-nine had had subsequent x-ray examinations. Twenty reported that their lesions had shown no change from the examinations made at the sanatorium. Four have since shown extension of their lesions and two of them have spent some time in a sanatorium as patients. Forty-seven of the fifty-three students in this group had shown no evidence of clinical tuberculosis subsequent to their graduation. There had been no deaths from tuberculosis among the 526 who trained at the sanatorium. Tuberculosis has never caused a proportionately large number of deaths among physicians. Physicians have always been more or less exposed to tuberculosis, but statistics do not show a high death rate among them, which seems to support the assumption that there is a relatively low morbidity rate.

Mediastinal Hodgkin's Disease—Kasabach and McAlpin point out that 251 patients were admitted to the Presbyterian Hospital and Vanderbilt Clinic between 1918 and 1935 with the diagnosis of Hodgkin's disease. Seventy-seven had mediastinal involvement. The cases in which the mediastinum was involved were analyzed in order to determine what relation there might be between treatment and the length of survival. In nineteen of the seventy-seven cases the presenting manifesta-

tion of Hodgkin's disease was found in the mediastinum, as shown on roentgenograms, without associated lymphadenopathy elsewhere. In these cases enlargement of peripheral lymph nodes became apparent on an average of eighteen months after the x-ray diagnosis of mediastinal adenopathy. In the remaining fifty-eight patients with mediastinal involvement, Hodgkin's disease was present in various parts of the body at the time of the first examination. Of the seventy-seven patients, twelve have been lost to follow up and fifty-seven have died. The remaining eight are living and two are at present in the terminal stage of the disease. The average survival period of the group receiving adequate irradiation is five years and four months. Twenty patients had what was considered inadequate treatment. Their average survival period was approximately three years and three months. The remaining seven patients had no treatment. The average survival period in this group was approximately three years and one month. The more generalized the disease, the shorter is the period of survival. Osseous invasion, pulmonary and pleural complications, and enlargement of the liver are associated with shorter period of survival. The maintenance of the patient's weight and general well being is stressed as an important factor in the prolongation of life.

Treatment of Congenital Syphilis with Acetarzone—During the last two years Smith and his co workers have used acetarzone in the treatment of thirty-three cases of congenital syphilis. There have been few toxic reactions. Whenever a reaction has occurred a rest of one week has been instituted and treatment resumed with a lower dosage. The method of administration has been a modification of the Bratusch-Marran scale. 5, 10 and 15 mg daily per kilogram of weight, each for a period of two weeks, then 20 mg for twelve weeks. Each prescription is made up in 56 cc of water so that 1 drachm (4 cc) a day gives the dosage and allows for fourteen doses. At the end of each course a Wassermann test is made and if the patient is given a rest period of one month, during which time mercury with chalk is taken. This is given according to the method outlined by Jeans. If the Wassermann reaction is negative, another course is given and the Wassermann test is repeated. If this too is negative a final course is given and then the parent is requested to return with the child every six months for a checkup for the next two years. Of ten patients who began their treatment after they had passed their first birthday, five became serologically negative and five remained positive. However, every child showed clinical improvement. Of the twenty-three children less than 1 year of age nine

became serologically negative and four remained positive after one or more courses. Of these four, one died of pneumonia during the second course, one had only one course of therapy, and the remaining two were irregular in attendance at the clinic. Of those who became negative, eight required more than one course before there was a reversal of the Wassermann reaction. There is not a single child in either group that did not improve under treatment.

Sulfanilamide Rash—A toxic effect, consisting of nausea, fever, dizziness, itching of the skin, cyanosis and cutaneous eruption, produced by the administration of sulfanilamide, is reported as occurring in three cases treated by Mainzer. The reaction appeared in two patients between the seventh and ninth day, but in one the first symptoms came on the second day. The symptoms began with fever and itching of the skin, followed by nausea, cyanosis and a cutaneous eruption. The temperature ranged from 101.4 to 104.3 F reaching its normal peak on the third day. Cyanosis of the lips was observed, which is attributed by various writers to the presence of methemoglobinemia or sulfhemoglobinemia. The rash was most prominent on the chest, abdomen face and extremities. The eruption was of the maculopapular type slightly raised from the unaffected skin and red or brownish. The lesions ran a rapid course fading out almost completely within nine days of onset. The evidence that the eruption was produced by sulfanilamide is strong, owing to the fact that when the drug was discontinued the symptoms faded out.

Diethylene Glycol Poisoning—Lynch describes four cases resulting in death from the ingestion of the new "elvan" preparation of sulfanilamide in diethylene glycol solvent. It appears that the lethal constituent was diethylene glycol, apparently used by the manufacturer simply as a solvent. Study of the necropsy material from these cases reveals an interesting and somewhat unique picture, similar to that produced by certain other poisons and yet apparently distinct. They may be summed up as showing in common a characteristic acute necrosis of the secretory tubules of the kidney and an equally characteristic central lobular necrosis of the liver, both conditions apparently based on direct epithelial damage. Two cases showed infarction of the renal cortex, in one complete in both organs, like embolic infarction and apparently resulting from vascular closure in the areas affected. In at least one case there was an acute gastritis in which the glandular epithelium of the stomach was damaged just like that of the kidney and liver. All the patients had an early acute lobular pneumonia by the time of death.

Treatment of Parkinsonism with Cobra Venom—It is generally accepted that cobra venom is a neurotoxin which strikes the higher nerve centers of the brain. The use of cobra venom solution in the treatment of the parkinsonian syndrome suggested itself to Gayle and Williams because it has been proved that intramuscular injections may relieve chronic pain, and in view of the fact that certain patients having paralysis agitans suffer from pain, it was decided to use this product in the hope of relieving parkinsonism. It was found in certain cases of the parkinsonian syndrome that not only was the pain relieved but certain other symptoms, such as increased spasticity and tremor were benefited. Cobra venom was used for eighteen patients with well developed signs and symptoms of the parkinsonian syndrome. They exhibited the typical signs of muscular rigidity nonintention tremors, masked facies, pains and altered gait. The ages of the patients varied from 21 to 69 years. The method of treatment followed in each case was to give the patient 0.5 cc of cobra venom intramuscularly the first day and then 1 cc every other day for ten doses. If no subjective improvement was effected by this number of doses, the treatment was discontinued. In all who showed improvement, the interval between doses was lengthened with no increase

in symptoms. The most striking effect of the cobra venom was the relief of pain. Usually the pains were relieved after about the fourth or fifth injection, and this has lasted until the present time. In 67 per cent of the cases there was marked subjective improvement, but little objective change was noted. These patients stated that there seemed to be less muscular rigidity and that they were able to perform tasks which were impossible before treatment. An improvement was noted in their attitudes, in that they were encouraged, more cheerful and decidedly less nervous. Thirty-three per cent of the patients who showed no improvement were older than the average and the duration of the disease was much longer. Cobra venom solution is a valuable aid in the symptomatic treatment of the parkinsonian syndrome, it has a cumulative effect when given in small doses intramuscularly and it can be partially substituted for drug therapy in certain cases of the disease.

Ulcers from Varicose Veins and Lymphatic Blockage—Trout believes that for the successful treatment of intractable ulcer due to varicose veins and lymphatic blockage the removal of the diseased tissue, in addition to the removal of the fascial barrier and the regeneration of the lymphatics, is essential. In addition to the work of Kondoleon there has been much experimental work to show conclusively that lymphatics do regenerate. The beneficial results following the removal of the fascia might be due to having the superficial tissues drained by the deep lymphatics. It is the author's belief that the edema and the like are due not only to the blockage of the venous system but also to the obstruction of the return of lymph. The obstruction of the lymph is due to the blockage of the lymph channels and nodes by the fibrous tissue which follows the infection. In such cases both the width and the length of the fascial strip removed should be greater than the amount of superficial fat removed, when the lymphatic block is confined to the superficial lymphatics. To establish a free path for the unhampered regeneration of the lymphatics, it is necessary to remove the strip of fascia higher than the edema and particularly is this true when the swelling is the result of involvement in the deep vessels and lymphatics. Of course, in these cases the strip of fascia is removed from both the inner and outer sides. Since 1917 the author has treated forty-one cases of intractable ulcers with success. By "success" he does not mean to imply that the leg has become normal or that it is as good as the opposite and unaffected leg. However, these patients have been relieved from pain, the ulcers have completely healed, the swelling of the leg has been greatly reduced and they have returned to their various occupations without any marked degree of physical discomfort or the necessity of wearing an elastic stocking or applying Unna's paste legging.

*Chin Retraction New Sign in Anesthesia J U Human—p 66

Chin Retraction—Human observed the occurrence of chin retraction about eighteen months ago in more than 50 per cent of the 600 patients he has anesthetized to the third stage of anesthesia. The sign consists of a downward movement of the larynx and chin with each inspiration. In cases in which the chin does not actually move, the tightening of the chin depressor muscles can always be either seen or felt just below the chin with the fingers. Usually the chin moves visibly. When eyeball activity ceases, the corneal reflex disappears and the pupil begins to dilate, chin retraction begins and, as the anesthetist always holds the mask with one or two fingers under the chin, he can feel the rhythmic tightening of the muscles under his fingers without looking at the patient and thus determine the degree of anesthesia. This sign remains active and obvious throughout the further deepening of anesthesia, and in ascending anesthesia it stops abruptly at the upper level of the second plane. The most reasonable explanation of chin retraction would be that the muscles, which by their tone hold the larynx in position, relax at the bottom of the first plane so that with each downward movement of the diaphragm the lungs are drawn downward bodily for about 1 cm carrying the trachea and larynx with their attachments downward with them. It occurs whether ether, chloroform or nitrous oxide is being given. Chin retraction is always more marked when a closed system of anesthesia with rebreathing is employed.

Trauma in Pulmonary Tuberculosis—Skolnick cites the case of a fireman who seemed to be in perfect health previous to an injury (exposure to adverse conditions of physical fatigue exhaustion and water drenching) as evidenced by his personal history, family history and occupational records. While he was working under extreme conditions of exposure there was a progression of his pulmonary tuberculosis. Although the symptoms were apparently present earlier the condition was not diagnosed as tuberculosis until approximately eight months following the injury. Medical authorities substantiate the opinion that external factors frequently bear an important causal relationship in the activation of dormant tubercle bacilli into the disease of tuberculosis.

Treatment of Acute Poliomyelitis—The new system of treatment in acute poliomyelitis that Mills describes has produced results over a period of twenty years so promising that it appears that one's views as to the degree of recovery for

sible will have to change. In opposition to the accepted theory the view is taken that the pain in the extremities is almost completely vascular in origin. The muscular pain results from venous engorgement and consequent anoxia of the paralyzed muscles. The venous return from the extremities is influenced mainly by tone and activity of the muscles. In poliomyelitis the interference with this venous return is often of extreme degree. At first there is venous stasis, and later on capillary stasis and capillary paralysis. As a result mild trophic changes develop in the skin, bones, joints, fasciae and especially the muscles. Immobilization of paralyzed limbs, with consequent vascular catastrophe, leads to contraction of the muscle sheath and anemia of muscle fibers, with subsequent mild fibrosis. The ischemic pseudoparalysis is accentuated by stretching and relaxation of muscles, tending to cause a permanent shortening of the length of the fibers and often resulting in slight deformities. The irritation stage is an artificial stage, which may invariably be overcome in two or three days by a well regulated system of frequent passive movement, fomentation and hydrotherapy. In no case does pain persist more than three days, although it will usually recur in the early mornings after the limb has been rested during the night. Cutaneous hyperesthesia also disappears under the treatment. As soon as the temperature drops, the active phase of reeducation is started, that is, reeducation is begun within one week of the onset of paralysis. The restoration of circulation is accomplished by hydrotherapy which makes use of the rapid alternation of hot and cold sprays in the bath. The limbs become suffused with pink within ten minutes, the areas last to lose their cyanotic appearance being those which overlie the paralyzed muscle groups. By this simple measure applied daily trophic changes are avoided and the later application of such operative procedures as sympathetic ramisection are rendered unnecessary. Briefly, instead of being dealt with by rest and immobilization in the acute stage, the affected limbs must be treated energetically, by fomentations, by hydrotherapy and by movement through every range of each joint every two hours, and a finely graded system of reeducation must be started as soon as possible, usually within the first week of paralytic manifestations. Under such a regimen wasting of paralyzed muscles occurs only to a small degree. It is not claimed that this treatment will cure all cases at all stages of the disease. So far only thirty-five cases have been treated in the early stages, but in view of the degree of improvement in these and in 1,400 chronic cases, it is claimed that Sister Kenny's methods will give the maximal recovery possible in every case treated within the first two months of the disease.

*Aural Vertigo. Clinical Study. A. J. Wright—p. 97.
Osteomyelitis of Petrous Pyramid. G. Kelemen—p. 113.

Aural Vertigo—Wright discusses seventy-three cases of vertigo from suppuration of the middle ear. The disease does not result from a lesion in the middle ear but is primarily in the labyrinth. It is marked by an increased irritability of the labyrinth, as shown in the cochlea by hyperacusis and in the vestibule by an abnormal reaction to normal stimuli, such as movements of the head, or to minimal abnormal stimuli, such as some alteration of tension in the middle ear. Focal infection is invariably present, and frequently other lesions exist, especially chronic iritis. All patients with aural vertigo treated by eradication of a septic focus or foci are now completely free from vertigo. The author believes that cases of labyrinthine vertigo, which have been regarded as of unknown or doubtful etiology, can be grouped together as belonging to a single disease which he calls "focal labyrinthitis." This disease is an inflammation of the labyrinth. He bases this view on the occurrence of nerve irritation, both auditory and vestibular, signs of tension and progressive loss of function, and on the analogy with a known inflammatory lesion, chronic iritis. It is not, in his opinion, the result of disease in the middle ear. That it is secondary to a focus of infection is shown by the invariable presence of such a focus and to a greater degree, by the arrest or even cure of the disease when such a focus

is eradicated. This he believes is the only hypothesis that explains the many isolated observations in the literature which do not fit into the present somewhat indefinite ideas of its pathology.

*Incidence of Weil's Disease Among Coal Miners in Northumberland and Durham. W. G. A. Swan and J. A. McKeon—p. 201.

Subcutaneous Spherules in Ehlers-Danlos Syndrome—Weber and Aitken believe that the presence of numerous freely movable subcutaneous spherules, especially where the skin is loose, may be included as a fifth main sign of the Ehlers-Danlos syndrome, though it has not been recorded in most cases. These nodules or "spherules" are usually the size of a pea or smaller and slip about under the skin, apparently in the superficial portion of the subcutaneous fat. By light pressure with the finger they can easily be moved an inch or considerably more without any pain or tenderness being complained of. Owing to their hardness one would not expect them to be lipomas, but by microscopic examination they have been found to consist of fat. The authors think that they are sprouting (budlike) lobules of subcutaneous fat, which by gradual thinning and atrophy of their pedicles become more or less free bodies in the loose subcutaneous tissue. Their presence in considerable number constituted the most remarkable feature of the case that they report. There were only a few of the "atrophic" scars which usually constitute the most important character of the Ehlers-Danlos syndrome. The Ehlers-Danlos syndrome is probably not so rare as is supposed. Since December 1936 cases from three families have been demonstrated before the dermatologic section of the Royal Society of Medicine in London, and other cases have been heard of from other parts of England.

Weil's Disease Among Coal Miners in Northumberland—In an effort to estimate the incidence of subclinical infection with *Leptospira icterohaemorrhagiae* among coal miners in the northeast of England, Swan and McKeon visited two collieries in the autumn of 1936. In one of these, six cases of Weil's disease occurred between February 1935 and December 1936. In the other colliery three cases had occurred in May and June 1936. In all the diagnosis had been confirmed by serologic agglutination. Among the miners at these collieries 101 volunteered to give blood for serologic examination. All gave negative agglutination results except two from the first colliery. These two men gave histories of a serious illness with jaundice eighteen months previously which seemed to be clinically identical with Weil's disease. Both their serums agglutinated to a titer of 1:300. The remaining ninety-nine men for the most part gave no history of any previous illness and none gave a history of anything in the least resembling Weil's disease. All their serums showed a negative agglutination at a titer of 1:30. These results are at variance with those previously published relating to sewer and fish workers. There seems to be no adequate explanation for this and the conclusion is that the incidence of subclinical Weil's disease among coal miners in the northeast of England is less than might have been anticipated.

Gonococcal Bacteremia and Cutaneous Lesions—Keil discusses a form of gonococcal bacteremia in which the patients often appear to be profoundly ill and in which the initial clinical impression seems consistent with a poor or guarded prognosis. This belief is strengthened when there are cardiac murmurs and the blood cultures are positive. Despite this, recovery is the rule. The course of these cases is often explained on the basis of healed gonococcal endocarditis accompanied by hemorrhagic cutaneous lesions, but the author's observations are at variance with this hypothesis. Although the literature contains isolated reports of this dermatosis, its diagnostic value has not been sufficiently recognized and in many instances the cutaneous lesions have been regarded as either a simple pyoderma, a drug eruption, a variant of multiform erythema or a nonspecific toxic manifestation. The cultivation of the gonococcus from the blood stream, joints, skin and other structures and its isolation after death from vegetations in the heart constitute evidence that this organism invades the circulation. An intermittent bacteremia is inadequate evidence that the heart valves are unaffected. It is probable that gonococci gain access to the general circulation through the superficial or deeper venous channels. The evidence for gonococcal bacteremia appeared to be unequivocal in four of the five cases cited, the organism having been isolated from the blood, articulations or cutaneous lesions. In the remaining instance the clinical course and the features of the eruption pointed to a systemic gonococcal infection. In general the syndrome is characterized by the occurrence of fever, joint manifestations and a special type of dermatosis. The condition has a duration of from several days to a few months, in some instances a protracted course is attributable to a residual, slowly healing deforming arthritis rather than to continuation of the bacteremia. The local focus from which dissemination takes place may be active and acute in other instances the primary process is clinically inactive and has apparently been healed for weeks, months or even years. There are no remarkable fluctuations of temperature such as are seen in the average case of gonococcal endocarditis. In many instances there is continued fever owing to the presence of an

arthritic process rather than to a persistent bacteremia. Articular disease is a fairly constant feature, with but few exceptions. The type of joint manifestation cannot be differentiated from that observed in ordinary uncomplicated gonococcal arthritis. The morphologic attributes of the dermatosis, considered in relation to the clinical picture, provide features that often lead the observer to diagnose correctly an illness otherwise obscure. The eruption is typically composed of a scanty number of lesions, varying from one or two to six or eight in all, in occasional instances they may be distributed over the entire body. As a rule the lesions are discrete, rarely does coalescence occur as an incidental event in the course of a profuse eruption. In typical cases the extremities are affected, with particular favor for their distal parts. Less commonly, isolated lesions are encountered on the trunk, face, scalp and oral mucous membranes, where they appear to be less easily recognized. The tendency to occur in crops is a striking phenomenon. In the majority of cases there were, on the average, two additional outbreaks of lesions. Generally the eruption arises during the febrile period, but rarely further development of lesions may be observed during intervals of apyrexia. The primary element is an erythematous macule that speedily acquires a central vesicle or pustule. In typical examples hemorrhage occurs in the center of the lesion, and in many cases the exudation of fluid and cells causes bullous formation. The classic lesion in full development is a hemorrhagic purulent vesicle or bulla, surrounded by a more or less broad erythematous areola. Occasionally an intermediary zone of relative pallor is noted. Exudation may at times be so pronounced that rupture occurs. A smear of the contents of a lesion reveals numerous pus cells in various stages of disintegration. Bacterial stains on cutaneous sections have their greatest field of diagnostic usefulness in cases in which the organism is difficult to isolate, but it will be generally necessary to study fresh or young efflorescences.

Nocturnal Hemoglobinuria with Hemolytic Anemia—Scott and his colleagues record two cases of the Marchiafava-Micheli syndrome of nocturnal hemoglobinuria with hemolytic anemia which were carefully studied during life and in which complete postmortem examinations were made. The clinical picture is clear cut and the main features are moderate hepatomegaly, anemia, hemoglobinemia, paroxysmal nocturnal hemoglobinuria, persistent hemosiderinuria and a liability to venous thromboses. The condition runs a protracted course and terminates in death. Splenectomy is without avail. The chief morbid anatomic changes are thromboses of the central veins of the liver with zonal hepatic necroses, marked siderosis of the renal tubules and erythroblastic hyperplasia of the bone marrow. It is suggested that these pathologic changes are the result of prolonged intravascular hemolysis. The possibility that some obscure chronic acquired hemolytic anemias may be larval forms of the Marchiafava-Micheli syndrome is suggested.

- Endocrine Disorders of the Skeleton G Coryn—p 228

Anomalies of Tuberculin Reactions—Paiseau and his associates point out that some investigators have called attention to the existence of negative cutaneous reactions in children or adults who have been in close and prolonged contact with carriers of tubercle bacilli. The authors themselves observed children living in prolonged contact with tuberculous parents who reacted negatively to tuberculin tests, not only to cutaneous reactions but also to intradermal tests with 0.1 cc of a 1:100 solution of tuberculin. In the course of the last three years the authors have collected seventeen cases of this type. The object of their report is not to expose the shortcomings of the tuberculin test but rather to call attention to certain anomalies: (1) long persistence of the dissociation between a negative cutaneous reaction to tuberculin and the positive intradermo-reaction to this substance, and (2) change of positive to negative cutaneous reactions. They discuss these anomalies and cite case histories in which they observed them. They reach the conclusion that it is indisputable that an organism which is free from tuberculosis never reacts to a cutaneous tuberculin test, but it cannot always be deduced from this that a negative cutaneous reaction is proof of the nonexistence of tuberculosis. Aside from that, there is a conclusion which has long been arrived at from the fact that a considerable proportion of subjects present a positive intradermal tuberculin reaction without a cutaneous reaction. What should be emphasized is that it is necessary to consider the change from a negative cutaneous reaction as evidence of a primary tuberculous infection.

- *Blood Transfusions in Chronic Tuberculosis of the Lungs Lymph Nodes and Serous Membranes J O Krizevski—p 1162

Blood Transfusion in Tuberculosis—Krizevski points out that as late as 1934 E Hesse of the institute for blood transfusion shared the opinion of Bürkle de la Camp and Schiff about the contraindication to transfusion as a variety of protein therapy in patients with tuberculosis. It was the author's object to determine to what extent blood transfusion can be employed in the treatment of tuberculosis. Moreover, it seemed desirable to know whether tuberculosis represents a contraindication to blood transfusion in patients in whom other conditions such as traumas make transfusions necessary. Before resorting to transfusions in the clinic, the author made experimental studies on the action exerted by blood transfusions on the evolution and propagation of tuberculous processes. He made these experiments on rabbits which had been inoculated with cultures of bovine and human tubercle bacilli. The observations on the rabbits convinced him that blood transfusion exerts no special action on the propagation and evolution of the tuberculous process. Nevertheless, the question of the possibility of an unfavorable action of blood transfusion in tuberculous patients had not been solved as yet. The great diversity of the forms of the tuberculous process, the various localizations and the forms of development raise the question as to the choice of patients and of the propitious moment for the transfusion. The author made his observations on seventy-nine patients. Transfusion can be resorted to in tuberculous patients when a concomitant disease or a traumatism indicates it. In such cases blood transfusion is contraindicated only in progressing chronic extensive cavernous tuberculosis. As a therapeutic procedure transfusion is indicated in the following cases: in serous disorders such as pleurisy with effusion peritonitis and polyserositis, in voluminous adenopathies and in focal pulmonary

tuberculosis with perifocal and pneumonic phenomena. Blood transfusion, however, is contraindicated in all forms of fibrous tuberculosis and in sclerosis of the lung. The most favorable time for the transfusion is that period of the disease when the resources of biologic immunity in the patient are in the ascending state. The blood transfusion should be repeated in cases in which the effect of the first transfusion is not sufficient. The author observed no parallelism between the effect of the transfusion and nonspecific protein reactions.

Acetonuria and Menstruation—Iselin says that in 1930 he first directed attention to a possible relationship between acetonuria and menstruation. He had observed that acetonuria occurs chiefly in little girls and that, moreover, its appearance is cyclic. He had also found that acetone was present in the breath of many women before and at the beginning of the menstrual period. His attention was again drawn to this problem by a case he observed recently. A girl, aged 15 years, had been subject to periodic vomiting since the age of 3 years. With the onset of the menstruation, the attacks ceased. The author considers the periodic acetonuria in girls before and after onset of the menstrual flow not so much a pathologic process as the sign of a physiologic-chemical process, of a menstrual acetonemia. This acetonemia might be elicited by a function of the incompletely developed ovary or, even more likely, by the hypophysis. At any rate, the author thinks that the periodic acetonuria is in some way connected with menstruation. This symptom, he says, is accompanied by a hypersensitivity to substances that impair the liver, such as chloroform anesthesia, and he advises that such substances should not be administered when acetone has been demonstrated in the urine of menstruating women.

Dextrose and Chlorides in Cerebrospinal Fluid—From their observations on eighteen patients, Canger and Radici found that the amount of dextrose and chlorides in the cerebrospinal fluid is increased during the postoperative period. The variations are not related to the type of anesthesia used and do not parallel those in the blood. Dextrose increases more in the cerebrospinal fluid than in the blood. It increases also if glycemia decreases. However, it never reaches pathologic proportions. The ratio of dextrose in the blood and the cerebrospinal fluid is diminished. The chlorides in the cerebrospinal fluid increase, whereas those in the blood plasma decrease. The ratio is diminished. The authors point out that the variations are due to dysfunction of the blood-central nervous system barrier which is concerned in the regulation of the passage of plasmatic substances to the fluid. The functions of the barrier are controlled by the stimulation of the chemical substances in the blood which depends on the more or less intense concentration of the substance, especially proteins in the blood plasma. The humoral variations induced by any surgical intervention, especially the proteins in the blood, are the cause of dysfunction of the blood-central nervous system barrier with consequent changes of the fluid. The authors believe that the modifications of the cerebrospinal fluid during the postoperative period are not related to the nervous disturbances which may appear in the course of the period.

Power of Absorption of Ureter—Grizzo experimented on rabbits to determine the power of absorption of the ureter, whether normal between two ligations or mechanically dilated without ligations. He concludes that the normal ureter constantly and rapidly absorbs solutions of india ink, bacterial emulsions and solutions of strychnine nitrate. The rapidity of absorption, in order of frequency, is strychnine solution, bacterial emulsion and india ink. The absorption of toxic doses of strychnine nitrate is more rapid when the poison is injected into the ureter than when it is injected subcutaneously. Absorption by dilated ureters takes place slowly. Solutions of strychnine injected into dilated ureters did not poison the animals, probably because of the slow absorption of the poison by the body and parallel rapid elimination of the poison. According to the author, the properties of absorption of the ureter play a part in the pathogenesis of infections of the urinary tract.

Elimination of Vitamin C in Tuberculosis—Nicita found that the elimination of vitamin C through the urine is diminished in patients who are suffering from pulmonary tuberculosis. The diminution is proportional to the seriousness of the general and pulmonary conditions of the patients. The consumption of vitamin C by the body is increased, owing to the presence of chronic tuberculous toxemia. The author points out the advisability of administering liberal amounts of vitamin C to patients who are suffering from pulmonary tuberculosis.

True Clinical Significance of Rovsing's Sign F. M. Bustos and C. J. Lebron—p. 206

Coagulation of Blood and Jaundice—Bustos states that patients who are suffering from jaundice show also a tendency to hemorrhages. The general opinion that the hemorrhagic disturbance is caused by the impregnation of the tissues by biliary substances is erroneous. The author made observations on several patients in whom a surgical intervention on the biliary tract had been performed. Some patients in the group had jaundice and others had not. The author found that drainage of the bile after cholecystostomy or choledocotomy induces a retardation of the coagulation time of the blood which is proportional to the amount of bile eliminated. The retardation is sometimes a half hour or more and is not related to the presence or absence of jaundice. If the eliminated bile is reintroduced in the stomach or duodenum of the patients by means of a duodenal sound, the coagulation time of the blood diminishes. The author emphasizes the fact that the cause of the hemorrhagic tendencies in the course of jaundice depends on the failure of bile to reach the intestine, which results in insufficient absorption of fats by the intestine with consequent diminution of the supply of vitamins to the body and disturbances of the calcium metabolism. It is not, as yet, ascertained which of the phenomena mentioned are caused by the absence of bile salts in the intestine and which of them are caused by that of bile pigments.

Significance of Rovsing's Sign—Bustos and Lebron state that Rovsing's sign is of no value in the diagnosis of appendicitis. Their opinion is based on a review of the literature and

cases from their own practice. The authors conclude that the sign is often missing in cases of appendicitis and may be present in intestinal diseases of patients who had an appendectomy. Two cases of the latter instance are reported in detail by the authors.

Ucko's Reaction in Diseases of Liver—Boccia and Gamalero state that the Takata-Ara reaction for liver functions is based on alterations of the proteins in the blood serum. The technic is as follows: Into four clean, small test tubes, each containing 0.2 cc. of the serum, are measured 0.1, 0.15, 0.2 and 0.25 cc. of a 0.36 per cent solution of anhydrous sodium carbonate. After shaking, the same quantities of a 0.5 per cent solution of mercury bichloride are added. The tubes are shaken again and allowed to settle for an hour and a half. Four different types of reaction can be observed: 1. A negative reaction, which is shown by the absence of precipitation in all four tubes or at least in three tubes, which remain translucent or slightly turbid. 2. Reaction 1 (+), the so called weakly positive reaction, which is shown by the presence of slight precipitation in the first three tubes. 3. Reaction 2 (++), the positive reaction, with precipitation in all four tubes. 4. Reaction 3 (+++), the intensely positive reaction, in which a thick precipitate forms in all four tubes immediately after addition of the reagents. The authors made the test on twenty-seven patients who had diseases of the liver and in twenty-five who had diseases other than those of the liver. They found that the test gives intensely positive results in ascites of atrophic cirrhosis, positive results in some cases of cancer, regardless of the location of the disease, and negative or slightly positive results in stasis of the liver and in the majority of cases of diseases other than those of the liver. The reaction of the third type shows in all cases of serious liver involvement and does not take place in diseases other than those of the liver. The authors conclude that the test is of value for diagnosis of liver insufficiency, especially if it is performed in association with other tests. In addition to the advantage of an easy technic, the gradation of the results of Ucko's modified reaction offers the possibility of evaluating with exactness the intensity of insufficiency of the liver.

Rickets and Vitamin D—Nadrai points out that Harnapp recommended the intramuscular injection of a single large dose of vitamin D, namely, between 12 and 15 mg., for the treatment of rickets. After reviewing the literature on the parenteral administration of vitamin D, the author describes his own experiences with the administration of the single large dose. His observations were made in thirty cases. His object was to determine the smallest dose which, in intramuscular injection, will cure rickets. He used the different types of vitamin preparations that are available on the Hungarian market and found that the freshly opened preparations are well tolerated if administered intramuscularly. The oil is absorbed within a few days. In some moderately severe cases he administered 10 cc., that

is, the equivalent of 3 mg of vitamin D (150,000 international units), while in other cases he administered as much as from 15 to 20 cc (45 to 6 mg). He found that 10 cc, or 3 mg, was generally adequate for the cure of mild and moderately severe cases and that from 15 to 20 cc was required for the more severe cases. In extremely severe cases and in those complicated by serious infections, such as pneumonia or influenza, the single large dose proved ineffective, probably because the organism is incapable of adequate storage of the vitamin. In such cases, which have to remain under medical control anyway, it is better to repeat the intramuscular injection after several weeks rather than to increase it. The author concludes that the administration of a single large dose of vitamin D is especially suited for prophylactic therapy.

Pseudocavitation in Children with Pneumonia—Wissler emphasizes that not every round area of lesser density in thoracic roentgenograms corresponds to an intrapulmonary cavity. His investigations on spontaneous pneumothorax, in which pseudocavitation is quite frequent, induced him to study this problem. He defines a pseudocavity as the roundish, sharply defined area of lesser density in shadowy portions of the lung, which, in view of the clinical picture, cannot be the result of destructive processes of the lung. He does not include those phantom formations which are the result of faulty exposure and those fine annular shadows which remain after certain pleural disorders. His observations were made on cases of pneumonia. He detected the pseudocavities in children of all ages, the youngest being 10 months and the oldest 13 years of age. They appear during or after defervescence and accompany the breakup of the infiltrate. They disappear rather rapidly, without leaving traces. Rather meager anatomic observations seem to indicate that the pseudocavities are caused by a circumscribed emphysema. If their pneumonic nature has been established, they have to be differentiated from pulmonary abscess and encapsulated pneumothorax. The decisive factors are the clinical aspects and the course of development.

Disturbance of Gastric Function During Skin Diseases

—Voss says that histamine, which is present in body tissues particularly in the skin and which is produced in increased quantities during inflammatory processes, exerts an intensive action on the gastric secretion. Since some cutaneous disorders are accompanied by a disturbance in the gastric secretion, he and H Voss examined the gastric juice of 200 patients with inflammatory skin diseases. They found practically a parallelism between the acidity of the stomach and the degree of inflammation and of the extension of the skin disease. The more acute and extensive the inflammation, the higher were the values of gastric acidity. It was assumed that the hyperacidity was the result of a liberation of larger amounts of histamine, or of a similarly acting substance, by the inflamed cutaneous tissues. In chronic skin diseases, however, hypoacidity or anacidity was observed. Since gastritis and ulcers can be produced by chronic injection of histamine, it may be assumed that the histamine-like substances liberated in the course of skin diseases may lead to an impairment of the gastric glands. Summarizing his observations in animal experiments, he says that the stomach of rats reacts to a single histamine injection with an increase in gastric juice and in acidity. In case of chronic administration of histamine, the quantity of free acid decreases to complete anacidity. Then it could be observed that the inhibiting action of histamine on the activity of the gastric glands is dependent more on the continued and uniform administration of histamine than on the absolute quantity of histamine, that is, the conditions were like those that were found in the inflam-

matory skin diseases. The authors also experimented with roentgen and quartz lamp irradiations. The object was to determine whether the gastric glands could be influenced by an experimentally produced chronic inflammation of the skin. It was found that two weekly roentgen irradiations, continued for a month, as well as quartz lamp irradiations, resulted in complete anacidity of the gastric juice.

New Medium for Mycologic Cultures—Memmesheimer says that a shortage of peptone was an inducement to develop, in addition to the commonly used culture mediums of Sabouraud and of Gruetz, one in which peptone was not necessary. It was found that the skin of guinea pigs can be utilized in the preparation of a mycologic culture medium. The hide of a guinea pig (skin and hair) is cut to pieces and is cooked for from thirty to forty-five minutes in caustic potash solution. To from 75 to 80 Gm of hide, 20 cc of a 30 per cent solution of caustic potash and 75 cc of water are added. The cooking with the caustic potash solution dissolves hair and epithelium, and the rest consists of connective tissue. The material is filtered through muslin and neutralized with hydrochloric acid. While this is done, hydrogen sulfide escapes. Then follows filtration through filter paper or cotton. To prepare the culture medium, the filtrate is diluted with water to make 1,000 cc. Then 40 Gm of maltose and 18 Gm of agar are added. This culture medium corresponds to the "milieu d'épreuve" (test medium) of Sabouraud and Gruetz (medium I). However, the extract of 75 or 80 Gm of guinea pig hide, following neutralization and filtration, may be diluted with water to make 500 cc and then combined with 9 Gm of agar. This medium corresponds to the "milieu de conservation" (medium of preservation) of Sabouraud and Gruetz (medium II). If the extract is not to be used at once, it may be concentrated, dried and pulverized. After describing how culture mediums are prepared from this powder, the author discusses his experiences with the culture mediums. Materials from forty patients with a suspected mycosis were tested simultaneously on the culture mediums of Sabouraud, Gruetz and the described medium I. In sixteen of these patients the cultures yielded epidermophyton (usually Kaufmann-Wolf), but whereas the described medium showed this fungus in fifteen cases, the other two mediums showed it in only ten cases. Material of eight of the fungus-positive cases was tested also on the maltose-free medium II. This medium likewise yielded the fungus. The new medium proved valuable also in studies on the dissemination of epidermophytosis. The author says that growth was detectable sooner on the new medium than on the medium of Gruetz. *Microsporon audouinii*, *Microsporon flineum*, *Achorion quinckeanum*, *Trichophyton gypseum*, *Trichophyton rosaceum* and *Epidermophyton rubrum* likewise showed typical growth and color formation on the new medium I. On the new medium II (free from maltose) growth and color formation were less profuse.

Beriberi in Germany—Broder and Engel say that completely developed avitaminoses are comparatively rare in Germany. If avitaminoses do develop, the prolonged adherence to an extremely restricted diet plays a part and the carbohydrate portion is especially important. As early as 1884 Takaki of Japan pointed out that there seems to be a malproportion between proteins and carbohydrates in the development of beriberi. In recent years Abderhalden and Wertheimer have discovered relations between vitamin B₁ and the carbohydrate metabolism. After citing observations from the literature in which one-sided diets consisting chiefly of carbohydrates

led to the development of avitaminoses with polyneuritic symptoms, the author reports a case of his own observation. It concerned a girl, aged 14 years, who, in order to lose weight, had restricted her food intake to from two to four slices of bread with margarine and sugar. With this she drank highly sweetened cocoa prepared with water. This food she took in the evening, during the day she ate nothing, but she performed rather hard physical work in a tree nursery. Her weekly consumption of sugar was between five and six pounds. The girl continued this absurd diet for three months. Gradually her appetite decreased, she had attacks of nausea, suffered from constipation, had cardiac palpitation and felt extremely fatigued. Swelling of the ankles and legs appeared. Several weeks later, numbness developed in the legs, and walking and standing became insecure. After hospitalization the girl at first refused adequate amounts of a mixed diet, but gradually her food intake became normal and she even requested fruits and vegetables between meals. Specific therapy in the form of a daily injection of vitamin B₁ was begun immediately after admission to the hospital. In addition to this, the vitamin was given also by mouth in the form of tablets. After an initial loss in weight (elimination of the retained water) the girl gained weight. The numbness in the legs persisted for weeks and the insecurity in walking was still observable after two months. Formication and drawing pains in the legs and attacks of tachycardia occurred from time to time. The author suggests that with the absurd diet other deficiencies besides that of vitamin B₁ play a part, however, as the result of the excessive intake of sugar the deficiency in B₁ was most pronounced.

Temporary Pulmonary Infiltrates as Hyperergic Tissue Reaction—Busche says that localized hyperergies are much more frequent than generalized allergy. He points out that recently disorders have been observed, which become manifest in a rapidly disappearing infiltration of the lungs and a high eosinophilia of the blood and which probably belong to the group of localized hyperergies. The author observed a man, aged 47, who in working near a circular saw had lost a thumb, three fingers and part of the hand. The wound healed without complications, but after about three weeks of treatment the patient suddenly acquired fever, the cause of which was at first obscure. The patient's general condition was not impaired, he complained only of a slight cough. Roentgenologic examination of the thoracic organs disclosed a massive infiltration in the region of the middle field on the left side. However, in spite of the positive roentgenologic aspects the physical examination revealed hardly any sign of disease of the lung. The small amount of yellow sputum was found to contain some eosinophilic cells and a mixed bacteriologic flora, but never tubercle bacilli. Examination of the blood disclosed a mild hypochromic anemia. The total number of leukocytes was 10,300. The differential blood count revealed an enormous eosinophilia of 29 per cent, and the sedimentation speed of the blood was greatly increased. Intravenous and oral administration of calcium was followed on the second day by disappearance of the fever, and the roentgenologic control revealed that, aside from a slight intensification in the vascular outlines, the pulmonary infiltrate had disappeared. Further blood control showed that the eosinophilia increased still more and reached a total of 38 per cent. Several successive roentgenologic examinations of the lung gave completely negative results, as did also the sputum tests for tubercle bacilli. The sedimentation speed of the blood became normal again, but there still existed an eosinophilia of 7 per cent. The peculiar course of the disease together with the severe eosinophilia suggested an allergic reaction, and cutaneous tests were made to determine the offending allergen. However, all such tests were negative. The author cites another case in which a temporary pulmonary infiltrate concurred with an increase in eosinophils. He thinks that this syndrome might be more frequent than was assumed and cites similar observations by Löffler. Moreover, Engel in Japan observed cases of so-called priver cough during the months of May and June. This disorder, which is considered as an allergic reaction to pollen, is likewise accompanied by temporary pulmonary infiltrations. The author says that Löffler regarded the process as a benign tuberculous one and that Swiss authors observed pulmonary infiltrates of short duration in

patients with tuberculosis. However, he emphasizes that in the majority of cases a relationship to tuberculosis has not been proved and that more observations will be necessary to arrive at a complete causal explanation.

*Method of Staining Erythrocytes in Urinary Sediment A. W. Endtz—p. 141

Staining Erythrocytes in Urinary Sediment—Endtz says that, if there are only a few erythrocytes in the urinary sediment, errors may be caused by bodies such as yeast cells, algae, lymphocytes and other formed elements. The author succeeded in finding a method which will avoid such errors. He prepares two stock solutions: the first consists of 1 part of benzidine in 100 parts of diluted alcohol, the second consists of 20 parts of a 6 per cent solution of acetic acid in 100 parts of distilled water. The reagent that is used for staining the erythrocytes is composed of 1 cc of the first solution, 2 cc of the second solution, five drops of a 3 per cent solution of hydrogen peroxide and 9 cc of distilled water. Following centrifugation of the urine, the fluid is carefully poured off so that as little as possible remains in the sediment. Then a drop of the reagent is put into the centrifuge tube and, by slight tapping, is mixed with the sediment. If a urine contains much sediment, it is advisable to place a drop of it on a slide and then add a drop of the reagent. The two drops are mixed by drawing the cover glass in the oblique position back and forth over the slide. Inspection of the stained preparation reveals that all formed elements of the blood have turned blue, whereas yeast cells and all other elements not belonging to the blood remain unstained. The erythrocytes show a uniform blue with only a few isolated granules. The leukocytes show a blue nuclear stain, the protoplasm contains many blue granules. These granules may be so numerous and their coloring so intense that the nuclear stain may disappear among them. The large lymphocytes can be recognized by their round nuclei and by their protoplasm with many granules. The small lymphocytes are differentiable from the erythrocytes by their large number of granules. If a more distinct differentiation of the erythrocytes and leukocytes and of the various types of leukocytes is desired, it is advisable to use a reagent with a higher acetic acid content. The author recommends the following reagent: 0.5 cc of concentrated solution of benzidine (as indicated), three drops of a 3 per cent solution of hydrogen peroxide, five drops of distilled water and 5.5 cc of a 1 per cent solution of acetic acid. This reagent is best for the differentiation of the different types of blood corpuscles, but, if only erythrocytes are looked for in the sediment, the first mixture is the best.

Action of Vitamin A in Rickets—Burchard investigated whether it is advisable to treat rickets simultaneously with vitamins A and D. Since it was demonstrated that cod liver oil is of superior value in the treatment of rickets it was of interest to learn whether vitamin A is concerned in the antirachitic action of cod liver oil. The author points out that erroneous conclusions have been drawn in other investigations on this problem because it was overlooked that the preparation of vitamin A that were used contained also vitamin D. If

author treated one group of rachitic children with a preparation of vitamin A which contained also vitamin D₂ and a second group of children with vitamin D₂ only. In the latter group he used the same preparation, but the vitamin A contained in it had been destroyed. He found that the preparation of vitamin A which contains vitamin D₂ is an effective remedy for rickets, whether it is given unaltered or after destruction of the vitamin A content. The preparation in which the vitamin A had been destroyed produced the same increase in the anorganic phosphorus of the serum, but a greater increase than did the unchanged preparation in the roentgenologically demonstrable calcium deposits. The quantities of vitamin D₂ required for the cure of rickets were below the quantities of vitamin D, that is, of the form of vitamin D which is contained in irradiated ergosterol.

Wheal Test in Nutritional Disturbances of Nurslings—Schauer directs attention to the McClure-Aldrich wheal test and describes her experiences with this test in nurslings. First she reports experiences with the test in forty-two healthy and eutrophic nurslings and then in fifty nurslings with nutritional disturbances. She emphasizes that the wheal test should be made always under the same conditions, preferably while the children are fasting, and the site of injection and the technic should be always the same. In eutrophic and healthy nurslings the wheal time (time required for its disappearance) is determined by the age of the children, that is with increasing age the resorption time was retarded. Nurslings with nutritional disturbances but without clinical signs of loss of water had a prolongation of the wheal time. The wheal time was still longer in the nutritional disturbances that were accompanied by an acute or chronic exsiccosis, and the slowest disappearance of the wheal was observed in cases in which exsiccosis and atrophy concurred or when an intoxication existed. The author stresses that a single determination of the wheal time does not permit definite evaluations but that repetition of the test at intervals of several days provides a good insight into the water economy of nurslings with nutritional disturbances. In premature infants the wheal time is shorter than in full-term infants, even in later months, that is, the standard age values do not apply to prematurely born infants. A shorter than normal wheal time was detected also in nurslings with tetany, icterus and eczema, in a case of extensive edema after burns, in two cases of myxedema and in one case of diabetes insipidus. The author reaches the conclusion that if the wheal test is employed with the necessary criticism and care if an exact technic is used and evaluations are not based on single determinations, and if attention is given to secondary factors that may influence the disappearance of the wheal the method is helpful in the evaluation of nutritional disturbances in nurslings.

Clinical Experiences with Vitamin D₂—Folberth demonstrates that the crystallized vitamin D₂ which is obtained from irradiated 7-dehydro-cholesterol is identical with the antirachitic substance of cod liver oil. It is not identical with the vitamin D that is produced by the irradiation of ergosterol. The author cured various forms of rickets with vitamin D₂ and found that it was well tolerated. However, he has not yet demonstrated whether the antirachitic action of vitamin D₂ is definitely superior to that of vitamin D.

Short Wave Diathermy in Endocrine Disorders—Samuels points out that the use of organ preparations during endocrine disturbances is a substitution therapy. Although this form of treatment may have a prompt effect it is usually not lasting, for whereas the deficiency of one gland is compensated the related glands and the hypophysis are made inactive by the substitution therapy. The author shows that it is much better

to reestablish the equilibrium in the disordered endocrine system by stimulation or inhibition. He says that Dausset tried to accomplish this by general short wave therapy and that since Dausset's death he has continued to study the use of short wave therapy for this purpose. He shows that before short wave therapy can be begun the following points have to be clarified: 1 What gland is diseased? 2 What is the condition of the hypophysis and its surroundings? 3 Is the disturbance due to hypofunction or to hyperfunction? 4 Is the existing disorder reparable or irreparable? The author clarifies these factors by determining the reduction time of the oxyhemoglobin, as index of the hormone content of the blood, before and after stimulation of the different endocrine glands. To accomplish this he uses the cycloscope, the construction and operation of which he described in the *Journal of Obstetrics and Gynecology of the British Empire* (44 1036 [Dec] 1937, abstr THE JOURNAL, Feb 26, 1938, p 696). The figure, which is determined before the stimulation of the glands, is the initial number. If the function of the endocrine glands is normal, stimulation in the condenser field causes practically no changes. However, in case of dysfunction of an endocrine gland, the reduction figure that is determined immediately after the stimulation shows a greater or lesser deviation from the normal figure. In women the figures are usually determined in the following order: initial number, numbers resulting after stimulation of the thyroid, the hypophysis, the ovaries and the breasts and, if necessary, the numbers resulting after stimulation of the adrenals and the pancreas. The different figures are entered in a diagram and the resulting curve is designated as the endocrine electrodiagram. This diagram is valuable not only for the diagnosis but also for therapy. The author says that hypofunctional disturbances are cured by stimulating first the complementary gland and then the actually dysfunctioning gland, either by local or by general short wave therapy. In disturbances due to hyperfunction, he resorts first to indirect inhibition by applying short wave treatment to the antagonistic gland and after that he treats the hyperfunctioning gland in the condenser field. He was able to demonstrate that in many endocrine disturbances the primary cause of the disorder is in the mesencephalon, the diencephalon and the hypophysis. If short wave therapy is applied to the hypophysis, not only this organ but the entire mesencephalon is influenced and thus the various centers and tracts. The author points out further that there are numerous disorders in which a hypophysial involvement has not been suspected heretofore; he mentions migraine, bronchial asthma, diabetes mellitus and gastroduodenal ulcers. He was able to demonstrate, for instance, that following short wave treatment of the hypophysis the sugar content of the blood of patients with diabetes mellitus decreased rapidly.

Excitement of Examination and the Leukocyte Count

—Kellner directs attention to Farris's investigations of behavior of the white blood picture of students before, during and after examination and before and after football games. Farris found that the lymphocytes were greatly increased during the examination and before the game and believed that this was the result of the excitement caused by the examination or the game. In view of the fact that even extreme mental exertion causes only extremely slight metabolic changes and almost no changes in the white blood picture, Kellner decided to verify the observations made by Farris. Reasoning that the excitement is even greater before the examination than during it, the author examined the white blood picture of forty-five students on the day before the examination and a few minutes before. Because these tests did not corroborate the observations made by Farris additional tests were made on twenty students. In the latter group tests were made before and during the examination. In these cases a slight decrease (3 per cent) was observed. From these observations the author concludes that the excitement of the examination does not cause any essential morphologic changes in the white blood picture. In trying to explain the discrepancies between his own observations and those of Farris he points out that mistakes in counting or the absence of excitement in his subjects can be ruled out, because of the rather large number examined and because some of the students, who clearly showed signs of excitement, were free from lymphocytosis.

 Biologic Characteristics of Arterial Blood B Lidskiy—p 1288
 *Clinical and Anatomic Similarities of Amyloid Lipoid Nephrosis M I Frankshteyn—p 1323

Mechanism of Blood Transfusion—According to Vidos, there are a number of components other than the erythrocytes the importance of which in the blood transfusion is but little understood. Among them may be mentioned the hormones, the ferments and the electrolytes. The distribution of the albuminous components of the blood plasma, the degree of their assimilation and of breaking down both in the transfused blood and in that of the recipient have not been clarified. The author states that the results obtained with repeated blood transfusions in the treatment of anemia at the clinical division of the Moscow Institute of Hematology suggest that the dose, as well as the interval between the transfusions, has an important part. The effect seems to follow the law of Arndt-Schultze, namely, that weak stimuli increase physiologic activities while strong stimuli abolish them. In anemias resulting from failing hematopoietic function of the organism, the amount of blood transfused and the intervals between the repeated transfusions may result either in stimulation of hematopoiesis or in its inhibition. In order to avoid the negative phase, it is necessary to allow not less than from three to four days between the transfusions. Doses of from 200 to 300 cc are quite sufficient. The lower the color index of the blood, the more striking is the effect of the transfusion. The anhematopoietic and hypoplastic forms of anemia require numerous transfusions. The hemoglobin in these types, even after repeated transfusions, lags behind the number of the erythrocytes. To obtain the maximum therapeutic effect, the author advises, in addition to repeated transfusions, administration of large doses of iron with, in some cases, liver therapy. Blood transfusion is not indicated in the first days of an acute infectious disease. Indications for transfusion may appear in the subacute and the chronic state. Acute articular rheumatism and scarlet fever constitute the only exceptions. In these, transfusions are indicated in the first few days.

Similarities of Amyloid-Lipoid Nephrosis—Frankshteyn reports twenty-three personally observed cases of generalized amyloidosis and an analysis of similar cases from the post-mortem material of two large general hospitals in Moscow. This material embraces 285 deaths from chronic diseases complicated by amyloidosis. The cause of death was pulmonary tuberculosis in 36 per cent, chronic suppuration in 42 per cent (58 per cent of these were pneumosclerosis with bronchiectasis), visceral syphilis in 85 per cent, chronic colitis in 3 per cent, neoplasm in 3 per cent, recurring rheumatic endocarditis in 2 per cent, lymphogranulomatosis in 0.4 per cent and undetermined in 5.1 per cent. The clinical and microscopic studies of this large material reveal that nontuberculous pneumosclerosis with bronchiectasis has a prominent part in the etiology of amyloidosis. Enlargement of the liver and spleen and diarrheas are not necessary clinical symptoms of general amyloidosis. Pure amyloidosis of the kidneys is seldom seen at necropsy. It is characterized, when present, by the absence of clinical manifestations. Renal amyloidosis is associated in the majority of cases with lipoid nephrosis. The processes develop independently in the presence of the same chronic infections and manifest themselves clinically as amyloid-lipoid nephrosis. The lipoid nephrotic component leads to dropsy, albuminuria and cylindruria. In a number of cases, however, the amyloid-lipoid nephrosis, despite the progression of the lesion may run without edema but with albuminuria. Amyloidosis of the glomerular arterioles results in a secondary contraction of the glomeruli with symptoms of renal insufficiency. The rate of the development of amyloidosis and the destruction of the glomeruli vary. In the majority of the cases azotemia develops in the state of the large white kidney, resulting in part from the overloading of the organism with the broken-down albumi-

nous bodies. The clinical course of the amyloid lipoid nephrosis presents, as a rule, three stages: adequate renal function, lowered function and insufficient renal function. The lethal event in the majority of the cases takes place in the second stage and depends principally on the progression of the basic chronic infection. Renal amyloidosis affects the arterioles of the parenchymatous organs and as a local process does not lead to hypertension and to hypertrophy of the left ventricle of the heart or to pathologic alterations in the fundus of the eye. The cardiovascular syndrome is present only when the amyloid lipoid nephrosis is associated with arteriosclerosis or with nephritis. Microscopic hematuria was present in 40.3 per cent of all the cases of amyloid-lipoid nephrosis and in the majority of the cases was caused by the passage of the erythrocyte through the unruptured walls of the vessels.

 Irradiation with Hertzian Waves W A G Van Everdingen—p 284
 *Some Infants with Low Temperatures Refuse to Nurse J T Rademacher—p 289

Traumatic Arachnoiditis—Rademaker maintains that post-traumatic adhesions of the leptomeninges are more frequent than is generally recognized. This is proved by the fact that the complaints of the patients whose histories are reported in this paper were all erroneously diagnosed. Frequently the complaints are interpreted as "compensation neurosis." The author describes four cases of traumatic arachnoiditis: these patients frequently complain of headaches or pains in the neck, back or loins, and the complaints are often aggravated by physical exertion. They may appear more than a year or even several years after the trauma. Other symptoms are sensory disturbances of a radicular extension, reflex disturbances and impairment of the motility. The author shows that a correct diagnosis is possible only with the aid of a test with iodized oil. Surgical treatment produces cure or considerable improvement in some of the cases.

Plethysmometry of Nose and Patency of Sigmoid Sinus and Jugular Vein—Van Dishoeck directs attention to the fact that, in case of obstruction of one jugular vein by means of unilateral compression of the neck, the inferior concha of the same side of the nose becomes swollen, because the venous blood coming from the endocranium causes a congestion of the pterygoid plexus. In some cases this swelling can be detected by anterior rhinoscopy, but by means of an especially constructed nasal plethysmometer the swelling can be detected in nearly all these cases. The author describes and illustrates this nasal plethysmometer. He shows that because the swelling can be detected in nearly all cases, it can be utilized as a symptom of obstruction of the jugular vein and of the sigmoid sinus in cases of thrombosis, of pressure by brain tumor or brain abscess and of congenital absence of the sinus or jugular vein. In this case the symptom will be negative on the side of the obliteration and strongly positive on the other side.

Infants with Low Temperatures and Refusal to Nurse—Rademacher points out that in infants who refuse to nurse a low temperature is often the cause, for the rectal temperatures of such nurslings have been found to be 36.2 C (97.2 F) or even lower. Warming by means of hot water bottles has been found to be effective to counteract the aversion to nursing. After citing several cases that he himself observed he reports studies on this problem, which were carried out on a larger material. On the basis of the body temperatures and the nursing record, this material is divided into four groups. To the first group belong nurslings with low temperatures who refused to nurse, to the second group belong those with low temperatures who nursed normally, to the third group belong those with normal temperatures who nursed satisfactorily and to the fourth group belong those of normal temperature who refused to nurse. The last mentioned group included infants who were born prematurely, some who were under eight months with mongolian idiocy and weak nurslings with low vitality.

A SURVEY OF BLOOD TRANSFUSION IN AMERICA

PHILIP LEVINE, M D
AND
EUGENE M KATZIN, M D
NEWARK, N J

The occasion of the second International Congress for Blood Transfusion (Paris, September 1937) served as a stimulus for inquiry into the present status of blood transfusion in America. It was planned to obtain the necessary information through a questionnaire to be circulated among all hospitals approved for internship by the American Medical Association. Accordingly, the board of medical control of the Blood Transfusion Betterment Association of New York City authorized the following questionnaire, which was mailed to about 700 hospitals, 350 of which responded.

- 1 Blood group classification, check terminology employed
International (O, A, B, AB)
Jansky (I, II, III, IV)
Moss (IV, II, III, I)
- 2 Number of transfusions performed in 1935, in 1936 ?
- 3 Method of transfusion, indicate the technic employed
Citrate method
Lindeman method
Paraffin method
Syringe-valve method

| | |
|--|----------------------------|
| Specify instrument employed | Unger Brines Scannel |
| insert name of instrument if other than listed | |
- 4 Who performs the transfusions at your hospital?

| | |
|---------------------------------------|---------------------|
| House staff | resident interns |
| Surgical staff | |
| Laboratory staff | |
| Transfusion team | |
| Open to all members of hospital staff | |

If transfusions are performed by house staff, is there any supervision? By whom?
- 5 Donors
 - (a) Is a donor agency maintained by
 - (1) Your hospital?
 - (2) Your county or state medical society?
 - (3) A nonprofit organization similar to the Blood Transfusion Betterment Association of New York City?
 - (b) Is a commercial donor registry available?
 - (c) Are donors supplied gratis for indigents, if family donors are not available?
 - (d) What is the cost of blood per hundred cubic centimeters?
 - (e) How often are Wassermann, Kahn or Kline tests repeated on donors?

- (f) Is a test for syphilis done just prior to the transfusion?
- 6 Selection of compatible donor
 - (a) By blood grouping alone
 - (b) By direct matching of donor and recipient alone
 - (c) Use of a preliminary blood grouping, followed by a direct matching
- 7 (a) Are "universal donors" used? rarely? frequently?
(b) Is any test done to exclude dangerous universal donors (persons having high-titered agglutinins in their serum)?
- 8 If figures are available, what is the incidence of post-transfusion chills?
- 9 Accidents following transfusions

- 10 General remarks for more detailed data or information on any of the above items or on features of the subject not indicated above, if necessary, attach another sheet

SUMMARIZED RESULTS OF THE QUESTIONNAIRE

1 *Blood Group Classification*—The summary of the replies to the question on classification is given in table 1.

The results show that the Moss numberings are most widely used at the present time, the Jansky and the International classifications are employed with about equal frequency. However, when hospitals using more than one of the classifications are included (table 2), the International classification is employed in 23 per cent, while the corresponding value for the Jansky numberings is 16 per cent.

According to Kennedy's¹ report of 1929, the International classification was employed in 49.5 per cent of 525 hospitals, in a study of ninety-nine hospitals, Mason² in 1931 reported an incidence of 5 per cent. Our study shows an increase in the use of the International classification during the past eight years, but it is disappointing to record that the majority of the hospitals still employ a confusing arbitrary nomenclature,³ in spite of the fact that in current scientific publications the International classification is used almost exclusively.

Obviously, any increase in the use of the O, A, B and AB terminology is a fortunate circumstance, since this classification, in contrast to the previous arbitrary numbers, is based on the universally accepted Landsteiner theory of two agglutinable substances, A and B, in the red cells. Thus, when one refers to the blood group of a universal donor as group O, it is made evident that the red cells are magglutinable by virtue of their lacking in agglutinable substances, and it is

1 Kennedy, J. A. Blood Group Classifications Used in Hospitals in the United States and Canada. *J. A. M. A.* 92: 610 (Feb. 23) 1929.

2 Mason, J. M. *J. Med.* 12: 60 (April) 1931.

3 It may be noted that the International nomenclature was officially accepted by the National Research Council and the American Association of Immunologists in 1927 and by the League of Nations in 1928.

clear that persons with blood of groups A, B and AB have the corresponding agglutinable substances in their corpuscles

It is hoped that the present defect in nomenclature will be corrected in the near future by (1) teaching of the International classification in the medical schools and (2) regulation of donor agencies by the various local boards of health in conjunction with the state

or county medical societies. The latter measure indirectly stimulates the use of the International classification, which is recorded in the donor's identification book along with the systems by numbers. These two factors serve to explain the greater use of the International classification in New York City hospitals (fifteen of thirty-seven hospitals). Unfortunately the hospitals associated with the majority of American medical schools do not as yet employ this classification. In one hospital affiliated with a Western medical school the International nomenclature is taught to the students but the Moss classification is employed in the hospital records.

2 Number of Transfusions Performed in 1935 and 1936—Because of the difficulty of obtaining accurate hospital statistics, a detailed statement cannot be given. However, of 191 hospitals from which data were received, 77 per cent showed a decided increase in the number of transfusions in 1936 over the number in 1935. The remaining 23 per cent of the hospitals showed but a small decrease.

3 Method of Transfusion—Of the 348 hospitals which replied to the question, 136 employ but one method, and 172 use two methods in varying degrees of frequency, in thirty-six hospitals three different procedures are available and in four hospitals each one of the four recognized methods is used.

The summary of the compiled data is given in tables 3 to 7 inclusive.

The citrate method is most popular in American hospitals for several reasons, but particularly because no special precautions are believed to be required.

Curiously enough four hospitals, three of them in Ohio and one in Tennessee, employ exclusively the procedure with paraffin-lined containers. These four hospitals have bed capacities of 142, 270, 210 and 246 and in 1936 performed sixty-two, 340, 152 and 213 transfusions. Aside from Ohio, the procedure still has a certain degree of popularity in Massachusetts,

where the original method was described by Kump and Brown, and to a lesser extent in the Great Lakes region and also in California.

The Lindeman multiple syringe method is the choice of a number of hospitals in New York and New Jersey. This is not surprising in view of the past activity of Lindeman in popularizing his simple and efficient method in hospitals in and around New York. Analysis of the answers as to the use of some form of syringe valve apparatus for direct transfusions revealed that at least twelve different instruments are employed in American hospitals. It is noteworthy that the simpler types are by far the most popular. A small number of hospitals reported using several varieties of instruments. It is not the purpose here to recommend any particular instrument, undoubtedly a number of effective instruments with manually operated valves are commercially available. However, it seems necessary to condemn any apparatus based on the principle of the automatic ball-in-valve, on the ground that the formation of small clots in the ball-in-valve may result in the injection of the recipient's blood into the donor. As previously pointed out by Hartman⁴ with such instruments there is no guaranty of protection to the donor when patients with syphilis or any other infection of the blood stream are given transfusions.

It is significant that slightly less than half of all hospitals employ two transfusion methods. The most frequent combination, used in 136 of 350 hospitals, is the citrate method and one of the syringe-valve procedures. The ready availability of two methods apparently makes for a satisfactory and flexible arrangement, enabling the transfusionist to select a method which is considered to be more convenient or suitable in certain cases.

A small number of hospitals volunteered the information that the citrate method is employed in their pediatric service. For patients suffering from infec-

tions of the blood stream, the citrate method is used, apparently because it affords absolute protection to the donor. On the other hand, some of the advocates of the direct method believe that the advantages of the citrate method are more apparent than real and maintain that whole blood is preferable for patients with septicemia.

4 Who Performs the Transfusions?—Without going into detailed figures we may say that the questionnaires

⁴ Hartman, F. W. Instruments for Blood Transfusion. J. A. M. A. 84: 915 (March 21) 1925.

revealed that in the majority of the hospitals the transfusions are performed by the residents and interns under the supervision of either a resident or an attending physician

In only a small number of hospitals is the transfusion placed in the hands of a team of a small number of experienced workers. This ideal method of handling transfusions is popular in the metropolitan area of

New York. Of thirty-seven hospitals in New York City, twenty reported that a transfusion team is in charge.

In more than one third of all hospitals the transfusions are not in the hands of any one department but can be done by any member of the attending staff. One obvious disadvantage of this open policy lies in the difficulty of supervision. One cannot expect expert performance from physicians who carry out transfusions only occasionally. In a good number of instances transfusions are performed by the ever changing house staff with no supervision whatever.

5 (a) *Donor Agencies*—Of the 350 hospitals surveyed, 304 answered this question. Of these, 137 have their own list, recruited from their employees or from selected persons, fifty-three call donors from commercial agencies and sixty employ donors from their own list as well as from commercial agencies. Non-commercial donor agencies operated by the local board of health, the county medical society or both are located in but six large cities and two smaller ones. A small number of hospitals have at their disposal lists of volunteers, members of organizations such as the American Legion and the police and fire departments. The use of the radio for obtaining volunteers was mentioned in some instances.

(b) *Donors for Indigents*—Of 318 hospitals which answered this question, 190 supply blood to indigent patients, for the most part at the expense of hospital, local or state funds.⁵ No provision for supplying blood gratis to indigents is made in eighty-five hospitals, and forty-three other institutions offer this service only occasionally and when it is most urgently needed.

(c) *Cost of Blood per Hundred Cubic Centimeters*—The 319 answers to this question show that in just about one half of the institutions the cost of blood is \$5 per hundred cubic centimeters, in one third the cost is from \$7 to \$10. In a number of institutions the rate is somewhat higher for private patients.

5 In one of the state hospitals in the Middle West between \$25,000 and \$30,000 is spent each year for this purpose. In this hospital (bed capacity 954) about 1,000 transfusions were performed in 1936.

(c) *How Often Are Wassermann, Kahn or Kline Tests Repeated on Donors?*—Of the 350 hospitals circularized 136 did not answer this question. However, in a number of these 136 a routine test for syphilis was performed immediately prior to the transfusion. Ninety hospitals reported that such tests are performed on their donors at intervals varying from one to three months. In 112 institutions these tests are done at intervals of six months or longer.

(f) *Is a Test for Syphilis Done Just Prior to Transfusion?*—The results in table 8 show that in 178 of the hospitals some form of test for syphilis is performed just prior to the transfusion. In the remaining 172 hospitals, either there is gross negligence or the factor of safety depends on the frequency of routine tests for syphilis carried out by the organization supplying the donors.

A correlated study of the frequency of routine tests for syphilis and of the test done just prior to transfusion reveals that 179 institutions attempt to protect their recipients from transfusion syphilis by the routine use of the pretransfusion test, of this group fifty-three hospitals are supplied with donors whose blood is examined at intervals of six months or less. In ninety-one hospitals the pretransfusion test is omitted and reliance is placed, so far as the serologic test for syphilis is concerned, on a routine test performed every six months or at shorter intervals.

There remains a group of seventy-one hospitals that are supplied by donor agencies where blood is tested but once, at varying intervals⁶ or at intervals greater than six months, and these same hospitals fail to have any test for syphilis performed just prior to transfusion. In this group there is, therefore, a serious danger of the transmission of syphilis. (It is obvious that a careful physical examination of the donor is another necessary prerequisite. Unfortunately, this item was not included in the questionnaire.)

6 *Selection of Compatible Donor*—The compiled data on this subject are recorded in table 9.

Undoubtedly the routine procedure of obtaining a compatible donor by a preliminary blood grouping followed by a direct matching of the donor's cells and the recipient's serum, has been firmly established. This is evidenced by the fact that 310, or 89 per cent, of the 350 hospitals employ the two procedures in their proper sequence.

6 Replies to the questionnaire from this group include the answers varies, seldom, occasionally and frequently.

Five hospitals report the use of a blood-grouping test alone.⁷ While this may be a safe procedure in most cases if the grouping serums remain potent and sterile, most workers are agreed that direct matching is an additional necessary precaution which serves as a check on the blood-grouping tests. It is especially urgent in view of the fact that the Moss and Jansky classifications are so confusing. There is still another reason for routine matching, it is the only known method of detecting the presence in the recipient's serum or

Of the thirty hospitals reporting the use of direct matching only, but three hospitals stated that they do the direct matching both ways, i. e., the more important test of the patient's serum and the donor's cells and also the test of the donor's serum and the patient's cells. It may be assumed that in the majority of the remaining twenty-seven hospitals only the more important cross test is performed. In these instances, the transfusionist does not know when or how often he is using universal donors.

It may be considered remarkable that from this series of thirty hospitals, two severe reactions were reported, details of which are not available. However, it is a well known fact that when incompatible blood containing weak agglutinogens is injected into a patient with weakly acting agglutinins the transfusion may be carried out apparently without untoward results, at least so far as immediate symptoms are concerned.⁸

7 Universal Donors—A summary of the answers to questions dealing with the use of universal donors is given in table 10.

A consideration of table 10 shows that more than two thirds of the hospitals surveyed use universal donors "rarely" or not at all. Of seventy-nine (23 per cent) of the hospitals which reported the "frequent" or "moderate" use of such donors, only eight employ a test for the detection of the so-called dangerous universal donor. If one includes that larger group of institutions which use these donors "rarely" or "in emergency," only thirty-nine hospitals use any form of such a test.

In hospitals employing only the direct matching of the recipient's serum and the donor's cells, the transfusionist, as already pointed out, does not know when he is employing universal donors.

Universal donors are frequently used by one group of hospitals, and, in view of the rare application of the test to detect high-titered agglutinins, the dangerous donor must be used occasionally, and possibly with untoward results. In the section on post-transfusion reaction accidents to follow, three such reactions are

TABLE 9—Selection of Compatible Donor

| | |

atypical agglutinins which may be active against the prospective donor's cells.

In thirty hospitals grouping of the patient's and the donor's blood is usually omitted and selection of the donor is made solely by the direct test, which determines that the donor's cells are not agglutinated by the recipient's serum. If the additional precaution (as a rule omitted) is taken to determine that the donor's serum does not clump the recipient's cells, the two bloods belong to the same group, but such tests do not identify the group. While such a procedure insures a selection of compatible donors, it is frequently laborious and time consuming. It should be pointed out that direct matching alone will fail to detect the incompatibility—which is not so very rare—due to weak agglutinins in the recipient's serum and weak agglutinogens in the donor's cells, for instance the incompatibility shown by a recipient of group O whose serum contains a weak anti-A and a donor of group A, subgroup A². The advantage of a preliminary grouping lies in the fact that with the use of potent grouping serums such incompatibility would be readily detected.

Consequently it seems essential to perform grouping tests with potent serums and, after selecting a donor of the same group as the recipient, to perform a direct matching of the latter's serum and the prospective donor's cells. The results of direct matching should confirm the compatibility. If the grouping is correct, any clumping in the direct matching will reveal atypical agglutinins in the patient's serum active on the donor's cells. In this event one must select another donor, whose cells are not sensitive to the action of the atypical agglutinin. (Many workers believe that it is not necessary to test for the absence of atypical agglutinins in the donor's serum which may be active against the recipient's cells.)

As already mentioned, when direct matching alone is employed, the groups of the persons involved remain unknown. Yet it is curious that twenty-six of the thirty hospitals depending on direct matching alone said in the questionnaire that they use one or another of the blood group classifications.

⁷ In two of these hospitals direct matching is apparently never done (The number of transfusions performed in 1936 in these two hospitals is 351 and 340 respectively.) Of the three remaining hospitals one reported the use of direct matching in a few cases only another that direct matching is done only on the physician's request and the third that the test is performed only when there is doubt as to the blood grouping test. The number of transfusions performed in 1936 in the three hospitals is 120, 230 and thirty seven respectively. No accidents were reported by any of the five hospitals. However another institution reported two severe hemolytic reactions due to mistakes in blood grouping. These occurred before we began to do cross matching in addition to blood grouping. Donors were selected (at that time) by grouping only.

TABLE 10—Use of Universal Donors

attributed to the dangerous universal donor. Obviously, when a professional donor is employed or when a choice of several volunteers is to be made, donors of the same group as the patient should be used. (However, in those exceptionally rare cases in which a transfusion is most urgently required, any one of a previously prepared list of group O donors with low titered agglutinins may be used without any test.)

8 Incidence of Post-Transfusion Chills—Obviously in a survey of this character it is not possible to obtain sufficiently detailed data dealing with post-transfusion reactions and accidents. It may be stated also that the great majority of hospitals do not keep records of post-transfusion reactions in readily available form.

⁸ Grove E. F. and Crum M. J. J. Lab. & Clin. Med. 16: 257 (Dec.) 1930. Burnham Lyman. Transfusion from a Group II (A) Donor to a Group III (B) Recipient without Fatal Result. Arch. Int. Med. 46: 502 (Sept.) 1930.

However, from the material at hand, it is possible to state that of the 211 hospitals which responded to this question 135 (64 per cent) reported a low incidence of chills, i e, 1 per cent or less, sixty-two (30 per cent) reported an incidence of from 1 to 10 per cent and fourteen (about 6 per cent) an incidence greater than 10 per cent

A study of all hospitals using the citrate method exclusively indicates that these institutions reported either few or no reactions or else a relatively high incidence. This difference may perhaps be explained by the varying care taken in preparing the transfusion apparatus and the quality of the citrate solution employed. The meticulous care required for the successful use of the citrate method is described in detail in the paper of Lewisohn and Rosenthal⁹

9 *Accidents Following Transfusions*—Forty hospitals reported some form of accident that had followed transfusions, altogether there were sixty such accidents (sixteen deaths), which are summarized in table 11

The largest group of accidents was attributable to the injection of incompatible blood. These thirty-six accidents, with six fatalities, were reported from twenty-five institutions. In cases in which the transfusion was completed, or comparatively large amounts of blood were administered, anuria or jaundice were reported, in the majority of the cases, symptoms developed shortly after the transfusion was started

When one excludes three accidents due to the calling of the wrong donor or to the use of a random (non-tested) donor, there remains a group of thirty-three accidents reported by twenty-two hospitals, resulting from the injection of incompatible blood. One hospital, which reported two accidents, selected donors on the basis of blood-grouping tests alone.⁷ It is curious, indeed, that in the remaining twenty-one hospitals, which reported thirty-one accidents (with six fatalities), the incompatibility was not immediately detected although each of the twenty-one institutions reports the use of blood grouping followed by direct matching. Therefore one is led to believe that in the vast majority of instances the grouping serums employed are not potent and/or the persons performing the tests are not sufficiently trained

In two cases mild hemolytic reactions occurred in repeated transfusions with the use of the same donor. In another case the recipient had an atypical agglutinin active against the donor's cells. A report of the latter case was recently published by Culbertson and Ratcliffe.¹⁰

In this connection attention is called to the two accidents that resulted from the calling of the wrong donor. Such accidents have occurred when several transfusions were scheduled to be done within a short period. It is difficult to understand how a donor can be used without the hospital's resorting to any compatibility test whatever

Three accidents were attributed to the use of so-called dangerous universal donors, i e, persons having high-titered agglutinins in their serum. One of these was well described in a case report published by DeGowin.¹¹ In two of the three cases the recipient had pronounced anemia, in the third case, in which the recipient was suffering from burns, there was probably

concentration of the blood. In two of the hospitals involved, universal donors are used "rarely" and "frequently," respectively, but no test is performed to exclude dangerous universal donors. The third hospital reported the use of such a test only during the past year

Four cases are reported of transmission of disease from donor to patient, three cases of syphilis, in each case from a relative, and one case of malaria.¹² In one case, syphilis was transmitted from father to son. In this hospital donors on its own list are tested for syphilis but once, and no test is made on any donor just prior to the transfusion. In another hospital that reported the transmission of syphilis the present policy is to test the donors on the hospital list every three months and to perform a test just prior to the transfusion on nonprofessional donors only. The third case of the transmission of syphilis was reported to have occurred twelve years ago, at present a pretransfusion test for syphilis is done on all prospective donors

The case of malarial transmission was reported by one of the hospitals in the Middle West

One fatal accident was attributed to allergy. In this instance "a child allergic to cow's milk" was given a transfusion of compatible blood from "a donor who

TABLE 11—*Accidents Following Transfusion*

| | No of Cases | Fatal Cases |
|---|----------------|----------------|
| Incompatibility | 36 | 6 |
| Universal donor with high titered agglutinins | 3 | |
| Transmission of disease | 5 | |
| Allergic reaction | 1 | 1 |
| Poor transfusion technic | 3 | 1 |
| Death of donor | 1 | |
| Miscellaneous | 11 | 8 |
| Total | 60 | 16 |

had just previously ingested a large amount of cow's milk." No other details are available

Under poor transfusion technic is listed one fatal case in which the transfusionist gave "too large an amount of blood for the size, weight and age of the child." In another case death was attributed to an embolism, the method employed was a "direct pump transfusion." In the third case a child was given a transfusion through the fontanel, apparently there may have been a subdural or epidural hematoma

Under the heading miscellaneous are recorded four fatal cases of renal insufficiency in which there was no incompatibility. These were reported from the same hospital and were published by DeGowin.¹³ In another case death resulted after injection of 150 cc of compatible blood, the postmortem examination did not reveal the cause of death, which was recorded as "embolism or anaphylactoid." In one hospital two patients died with intense hyperpyrexia, the temperature being 112 and 115 F, ten and twelve hours, respectively, after the transfusion. Of the remaining four miscellaneous cases, one was fatal, death occurring after 50 cc of blood was injected, at postmortem examination chronic glomerulonephritis and secondary anemia were observed

Strangely enough, one hospital reported the death of a donor. To quote the report "The donor refused to

11 DeGowin E L Hemolytic Transfusion Reaction Produced by the Blood of a Universal Donor J A M A 108 296 (Jan 23) 1937

12 Another case of transfusion malaria reported from a hospital in the metropolitan area of New York has just come to our attention. The donor (father) gave a history of malaria forty years before with no recurrences. Our attention was recently called to two cases in which blood from syphilitic (professional) donors was transfused
13 DeGowin E L Osterhagen H F and Andersch Marie Renal Insufficiency from Blood Transfusion Arch Int Med. 50 432 (March) 1937

rest in the hospital immediately after giving blood, did rather violent exercise soon after and died of acute dilatation of the heart." The autopsy report recorded "fatty degeneration" of the heart.

It may be mentioned once more that the present data cannot furnish an accurate index as to the frequency of transfusion accidents. Undoubtedly some accidents were overlooked or were not reported in the questionnaires.

COMMENT AND SUMMARY

This survey reveals some increase in the use of the International classification. This scientific and logical system will undoubtedly become still more popular when a greater number of medical schools teach it rather than the arbitrary, confusing and meaningless numberings. (A survey of medical schools with regard to this question is contemplated.)

The general adoption of statutes, similar to those of New York and Wisconsin, authorizing courts to accept the results of blood tests in paternity disputes,¹⁴ will also stimulate the use of the International system, since it is difficult to discuss the genetics of the blood groups in terms of any other classification.

As already stated, the organization of suitably controlled donor agencies in New York City has been, at least in part, responsible for the frequent use of the International classification by New York City hospitals.

With regard to transfusion methods, it is noteworthy that about one half of the hospitals surveyed employ two methods, the citrate and one or another of the direct methods. Fortunately the great majority of transfusionists employing the direct method use either the multiple syringe procedure or one of the simpler forms of apparatus which are manually operated, and have avoided any apparatus in which the blood flow is regulated by a ball-in-valve mechanism.

In this country transfusions are for the most part performed, at least in ward cases, by members of the intern staff, under the sometimes inadequate supervision of a resident or member of the attending staff. Of course the ideal situation would appear to be that in which a transfusion team is employed in close association with the laboratory. However, with a rapidly changing house staff, such as is found in the great majority of hospitals, this apparently is believed to be possible only to a limited extent. Yet even under such conditions it is, in our opinion, feasible and practical that this work be done under the direct control of a small number of trained workers who instruct each new group of interns as they enter the hospital. Furthermore, the persons in charge might then form the liaison between the various hospitals, the local health department and medical societies to form a cooperative organization for the purpose of regulating professional donors and to serve as a center for the study of problems related to blood transfusion.

Some such cooperative action is required, since, as this survey reveals many institutions lack adequate control of syphilis in both professional and volunteer donors. Until American hospitals have at their disposal donors from carefully regulated agencies, it seems essential for each hospital to perform a recognized test for syphilis immediately prior to the transfusion. This, however, does not in any way relieve the transfusionist from the responsibility of a careful physical examination of the donor.¹⁵

Although the routine practice of selecting a compatible donor by a blood-grouping test of the prospective donor's cells, followed by a direct matching of the donor's cells and the patient's serum, is well established, reference to the section on post-transfusion accident, nevertheless, reveals that incompatibility of the blood still accounts for numerous avoidable accidents. It is probable that mistakes in selecting donors are attributable to poor laboratory technique in general and in particular, to the use of grouping serums that are not sufficiently potent. Unfortunately the source of the grouping serums was not investigated in this questionnaire, however, judging from our experience, it can be stated that in many institutions insufficient effort is taken to obtain potent serums.

Many unfortunate accidents might easily be avoided if a cooperative organization of hospital, medical society and local health authority, such as that suggested, would undertake to teach recognized laboratory procedures for compatibility tests. Such an organization might act as a local "registry" to which atypical blood could be sent for study and grouping and where transfusion accidents, so neglected at present, could be recorded and analyzed. Because of the widespread and increasing use of transfusions, these services, along with the control of the professional donor and measures to prevent transmission of disease by transfusion, are urgently necessary in the present American hospital program.

Beth Israel Hospital

THE BLOOD TRANSFUSION BETTERMENT ASSOCIATION OF NEW YORK CITY

ORGANIZATION AND FUNCTIONING OF THE ASSOCIATION AND ITS BLOOD DONOR BUREAU

DE WITT STETTEN, MD

Chairman of the Board of Medical Control and Vice President of the Board of Trustees of the Association

NEW YORK

The Blood Transfusion Betterment Association of New York City, with its Blood Donor Bureau was founded in 1929 under the auspices of the New York Academy of Medicine and with the aid of a small initial grant from Mr John D Rockefeller Jr. It is an expansion of the work of the Cooperative Blood Donors Bureau established at New York Hospital by Dr Arthur F Coca in response to a demand by hospitals and physicians for professional donors who have been reliably examined and thoroughly tested. Up to that time some individual hospitals and transfusionists had their own groups of donors, who were more or less carefully examined and tested, but most of the unsupervised and uncontrolled donors were supplied by commercial agencies, a large proportion of whose donors were frequently recruited from the less responsible elements of the community. Little consideration was shown for the welfare either of the donor or of the recipient. It became apparent that, in order to protect not only the patient from the receipt of incompatible or diseased blood but also the donor from ruthless exploitation and improper technical treatment, a more extensive community control was advisable. It was felt that, if a larger group of institutions and physicians were willing to cooperate in this matter by

¹⁴ Levine Philip Wisconsin Law on Blood Tests J A M A 105 1370 (Oct 26) 1925

¹⁵ Rein C R Wise Fred and Cukerbaum A R The Control and Prevention of Transfusion Syphilis J A M A 110 13 (Jan 1) 1938

Read in part at the second International Congress on Blood Transfusion Paris Sept 29 1937

employing donors through one agency, much could be accomplished. A large list of donors, including those with the rarer types of blood, would always be available, and they would always be under proper control.

The association is incorporated as a non-profit making organization. Its services are available to all the hospitals and physicians of the city. A board of trustees of nine members, most of whom are physicians and hospital executives is in control of the association. Professional supervision of the activities is vested in a board of medical control, thirteen physicians appointed annually by the board of trustees, to whom it is responsible. Five of the members represent, respectively, the New York Academy of Medicine, the New York Pathological Society, the department of health, the department of hospitals and the five county medical societies of greater New York. Most of the members of the board of medical control are experts either in hematology or in the practical aspects of transfusion or in both, and one of them is Dr. Karl Landsteiner of the Rockefeller Institute for Medical Research, the leading authority on blood grouping and the Nobel prize winner in medicine for 1930. His invaluable advice and assistance are always at the disposal of the association.

In 1930 the association cooperated with the committee on public health relations of the New York Academy of Medicine and the department of health in the formulation of sanitary code provisions for the control of professional blood donors.

HEALTH DEPARTMENT REGULATIONS

The sanitary code of the department of health of the city of New York defines the term "blood donor" as a person who offers his blood for transfusion purposes for a fee and lists the regulations by which he is controlled. A donor must be registered by the department of health. He must apply for registration on an official form supplied by the department, and at the time of application he must submit evidence that he has had a thorough physical examination by a duly licensed physician within the previous seven days. A prospective donor must be of normal weight, have normal blood pressure and show a negative reaction to the Wassermann test, given by the department of health. Certificates may not be issued to any person who has a history or symptoms of syphilis or malarial disease or who presents evidence of any disease of the heart, hyperthyroidism, asthma, status lymphaticus, tuberculosis, venereal disease or any other communicable disease or evidence of drug addiction.

At the time of certification, the donor is given an identification and personal record book, to which is affixed the seal of the health department and the date of registration. This personal record book contains a description of the donor and his blood classification, photograph and signature. In addition, there are entered in it the report on the Wassermann test of the blood made by the department of health at intervals of three months, the medical report on the physical examination and the donor's blood grouping. Subsequently there are entered the date of each transfusion, the amount of blood taken at each transfusion, the name of the physician administering the transfusion and the place where it was performed.

Hospitals and physicians not subject to hospital regulations must keep records of all the data pertaining to transfusions, and these records must be open to inspection by the health department.

Not only must the tests for syphilis be repeated every three months, but within the three weeks previous to each transfusion the donor must undergo a medical examination to check his physical condition and the hemoglobin content of his blood which must be at least 85 per cent. Furthermore, immediately prior to the transfusion, the physician making the transfusion must reexamine the prospective donor. If at any time the donor should be found lacking in the qualifications for which he is examined, his license may be revoked.

Except in emergencies only registered blood donors may be used.

In addition to these provisions, the sanitary code contains regulations relative to the control of blood donor agencies. These regulations require the licensing by the department of health of all such agencies, define the term "blood donor agency," and cover all the questions that are pertinent to their control. Agencies must keep records of all donors and the services which they perform. They may employ only donors certified by the health department, and care must be taken that a donor is not used too frequently. Licenses of agencies may be revoked for any violation of the sanitary code regulations.

ORGANIZATION OF THE WORK OF THE BLOOD TRANSFUSION BETTERMENT ASSOCIATION

The Blood Transfusion Betterment Association maintains a blood donor bureau, with offices, clinic rooms and laboratories, in a first floor apartment at 39 East Seventy-Eighth Street, New York. The professional management of the bureau is under the supervision of a salaried medical director, at present Dr. Arthur F. Coca, who was responsible for the formation of the association and who now supervises its technical and scientific activities. Dr. Coca is not a full time director but is assisted by a codirector, Dr. Eugene M. Katzin. It is planned in the near future to install in the bureau a full time resident medical director who will have complete supervision over the laboratory technicians. The business management of the bureau is directed by Dr. E. H. L. Corwin, secretary-treasurer of the association and executive secretary of the committee on public health relations of the New York Academy of Medicine.

Clinics for the examination of donors, conducted by thoroughly trained young physicians, generally recruited from the intern staff of one of the larger hospitals and under the supervision of a member of the board of medical control, are held five times a week. Extreme care is used in the examination of donors, and a high standard of physical requirement is maintained. Hitherto only men have been used, but it is planned to establish in the near future a small list of women donors for special needs, such as transfusions to be given to children and to women in religious institutions. The men have been recruited from among students, professional men and workers of all kinds, and they are in a position to answer a call and offer their services at any time of the day or night. Only those who have a telephone are accepted. Once accepted for registration with the bureau, they are kept under strict supervision, and arrangements for their services as donors are made only through the office of the bureau.

The prospective donor receives a preliminary examination for general appearance and suitability of veins, followed by a complete physical examination. The minimum weight acceptable is 150 pounds (68 Kg.). The blood is then taken to determine the blood group, the Wassermann reaction and the percentage of

hemoglobin For blood grouping the bureau uses the International, or the O, A, B and AB, designation established by Dr Landsteiner, because it is generally considered the most practical and the safest "Universal," or O, donors are separately classified into two groups, "safe" and "dangerous"

Until recently the Wassermann test, according to the statute, was regularly repeated by the department of health every six months, and the bureau further controlled the donor by a Kahn test taken every alternate six months, so that the donor received a serum test for syphilitic infection every three months Now that the regulation in the sanitary code has been amended by the department of health to the effect that the department must perform a test for syphilis every three months, the Blood Donor Bureau will control the initial Wassermann test of the department of health by a Kahn test and repeat the Kahn test when the donor returns to the bureau for reexamination after he has been used and before he is sent out for another transfusion It is felt that this method, coupled with a careful physical examination of the donor for evidences of active syphilis by the doctor performing the transfusion, and a rapid Kline test by the hospital laboratory just before the transfusion, is amply sufficient to safeguard against the transmission of syphilis More frequent compulsory tests would be a burden on the donor and might discourage their remaining on the lists

For the hemoglobin determination the Dare hemoglobinometer is used, and no donor is utilized whose hemoglobin falls below the required minimum of 88 per cent If acceptable, the candidate is photographed and application is made for registration at the department of health on a special form issued by the department When the passbook is received from the department the donor is ready to answer calls All donors must carry their passbook when responding to calls The passbook of donors from the bureau is specially stamped with the name and address of the association If for any reason the applicant is rejected by the department of health, he is not accepted for registration by the bureau

Donors are supplied with a pamphlet of instructions to insure cooperation on their part in the mechanics of the service and to give them information as to their conduct, habits and general health They must notify the bureau if they leave their telephones while on call, and a penalty of three months' suspension is imposed for tardy arrival at a hospital Every effort is made to safeguard the donor, as well as the patient, particularly against too frequent donation of blood, infection or the unnecessary cutting down on veins Each donor remains off the active list one week for every hundred cubic centimeters of blood given A notice is pasted in the passbook under the authority of the association, as follows

The "cutting down" on veins of donors supplied by the Donor Bureau of the Blood Transfusion Betterment Association is specifically *prohibited* by the rules of the Association as it is unnecessarily disabling, exposes the donor to the danger of infection, and tends to destroy his veins and render him unfit for further service Doctors using our donors will please observe this rule

Aside from a few trivial local infections of donors and an occasional complaint from a donor that there has been either unskilful puncturing of the vein or cutting down on the vein, there have been no real mis-

haps or accidents to donors in the seven years that the bureau has functioned, and in the past two years there have been no infections or accidents whatever

As of Jan 1, 1938, the bureau has an active list of 1,994 donors They are divided as follows group O, 946, or 47 per cent, group A, 732, or 37 per cent, group B, 232, or 12 per cent, and group AB, 84, or 4 per cent

The bureau functions in the following manner A record of each donor, with the results of his examination and blood typing, is kept in a card file for ready reference A second card index of the donors available and active, listed on different colored cards according to groups, is kept within easy reach of the attendant on duty The service is on a twenty-four hour basis, 365 days of the year Numerous emergency calls are received at the office nightly When a request for a donor is received, entries are made of the name of the patient, the name of the hospital and of the doctor performing the transfusion, or of the private physician, as the case may be, the type of donor needed and the urgency of the call If it should be requested and a specimen of the patient's blood is furnished, the donor's blood is crossmatched with it by means of the Landsteiner technic On receipt of a call the office attendant consults the card index and gets in touch by telephone with a donor who meets the requirements as to type of blood and any other necessary qualifications Subsequently the hospital is given the name of the assigned donor and the approximate time of his arrival Donors are sent by taxicab whenever the time element is especially important, and in all instances an effort is made to avoid unnecessary delay in transit by assigning a suitable donor from as near the hospital as possible

On receiving the telephone message the donor proceeds at once to the hospital, where he reports to the proper office and where his credentials are examined and his type is checked to make certain that he meets the requirements He is then examined, generally by the physician who is to give the transfusion, for evidences of any acute illness, particularly active syphilis If he passes he is usually required to sign a release absolving the hospital from any liability as a result of the donation of blood The following form, from Lenox Hill Hospital in New York City, is the type commonly used

To Whom it May Concern

Having been requested by the relatives and friends of to furnish blood for transfusion in her/his case, I hereby declare to do so voluntarily The Lenox Hill Hospital is in no way responsible for any consequences which may arise from the operation connected with the treatment, nor is the Lenox Hill Hospital responsible for any compensation whatsoever in the matter

Name

Witness

The donor's blood is crossmatched with that of the patient before the transfusion is given After the transfusion the donor is expected to rest for an hour He then proceeds to the cashier's office of the hospital, where he is paid for his services at the rate of \$7 per hundred cubic centimeters of blood, with a minimum charge of \$14, even for any quantity under 200 cc This rate has been fixed by the association as a fair compensation The record in the passbook of the amount of blood withdrawn constitutes a voucher

the cashier as well as a guide to the bureau as to the availability of the donor. For its services in supplying a donor, the association charges a flat fee of \$6 irrespective of the amount of blood used, which is billed to and paid by the hospital or private physician using the donor. After a donor has submitted to a transfusion he must remain off the active list for one week for every hundred cubic centimeters of blood given. Before he is used again, or if a three weeks period in which he has not been used has elapsed, he is given a complete reexamination at a bureau clinic, a fresh hemoglobin reading is made and the Kahn test is repeated.

GROWTH OF THE SERVICE

To give an idea of the response of the community to the Blood Transfusion Betterment Association, it is only necessary to cite the extraordinary strides made by the association in supplying donors, even through the severe economic depression. Donors have been supplied by the bureau and actually used, annually from 1930 through 1937, as follows: 1930, 3,125, 1931, 4,020, 1932, 4,852, 1933, 4,999, 1934, 5,216, 1935, 5,830, 1936, 6,686, and 1937, 9,280.

As will be seen from these figures, the work of the association has tripled since its formation seven years ago, and it still seems to be growing. All the municipal and most of the voluntary hospitals and numerous individual physicians in greater New York and some in the suburbs and neighboring towns have become its patrons. Private lists of donors kept by hospitals and doctors are gradually being abandoned in its favor. So great has been its growth that it became necessary last fall for the bureau to enlarge its quarters and to rent an additional apartment in the same building for more offices, clinic rooms and laboratory space.

The bureau has been making its own testing serums from high-titered bloods of selected A and B donors. To avoid errors the group A serum is colored red with eosin, and the group B serum is colored with methylene blue.

RESEARCH ACTIVITIES

As stated in the articles of incorporation of the association, its aims and purposes are:

The advancement of the science of blood transfusion, the furnishing of voluntary aid, exclusive of medical or surgical advice, to persons in need of blood transfusion, the classification of prospective blood donors and collecting information in regard to the same, the studying of the practice of the transfusion of blood in general, the conducting of investigations, experiments and researches generally to improve blood transfusion, all of the purposes being for the conservation of the public health insofar as it is related to the use of blood transfusion as a therapeutic measure, and the maintaining of a general organization to carry out the above purposes without pecuniary profit.

With these aims in view, in addition to developing a most effective blood donor service and preparing high-titered blood-grouping serums, the association has carried on, with its accumulated surplus funds, numerous other important activities. These have consisted of giving postgraduate training in both the technic of blood transfusion and the laboratory work of blood grouping and blood matching, of sponsoring and financially aiding important research in various aspects of transfusion, and of educating the public generally on the subject of transfusion.

In 1933 a committee on instruction of the board of medical control arranged for a series of lectures to physicians and laboratory workers by experts on the

"Technic of Blood Transfusion" and a second series on "Blood Grouping and Matching" and "Medicolegal Applications of Blood Groups." In addition, the medical director gave seven laboratory demonstrations at the bureau to small groups of physicians and laboratory technicians on "Methods of Blood Grouping and Blood Matching." These demonstrations were repeated recently.

Dr. Arthur F. Coca, the medical director, has made a study of the use of naturally immune and artificially immunized donors in the treatment of certain types of pneumonia. His theory was put to a test at the Harlem Hospital in New York City by Drs. Jesse G. M. Bullowa and William H. Park, under the auspices and with the financial aid of the association, but, unfortunately, did not yield any practical results, and for the time being the study has been abandoned.

Research in regard to the immunization of donors to staphylococcus and hemolytic streptococcus infections is being continued.

Dr. Coca has also made an exhaustive study of the problem of "universal" donors and has developed some new and safer serum tests, on which he reported at the second International Congress on Blood Transfusion in Paris last September.

The bureau is engaged in an extensive statistical study of (1) the indications for transfusion and (2) the causes of unusual post-transfusion reactions.

Under the direction of Dr. Philip Levine of the board of medical control and Dr. Eugene M. Katzin, a survey of the entire transfusion situation in the United States has been made by questionnaire, particularly to find out which method of transfusion is the most popular.

During the past year the association has rendered financial aid to Dr. Joseph Felsen of the Bronx Hospital, New York, in his studies on the use of immunized donors in the treatment of bacillary dysentery, to Dr. Fritz Schiff of the Beth Israel Hospital, New York, in his work on the duration of life of transfused blood in respect to "secretors" and "nonsecretors," to Dr. Thomas Hale Ham of the Thorndike Memorial Laboratory of the Boston City Hospital, Boston, for his research on blood transfusion and its effect on hemolytic processes, and to Dr. Philip Levine of the Newark Beth Israel Hospital, Newark, for his investigation of atypical agglutinins and their bearing on unusual reactions after blood transfusions.

This year a series of short pamphlets, written by members of the board of medical control, will be distributed to members of the medical profession of the city of New York by the department of health with its quarterly bulletin. The titles and authors of these pamphlets are as follows:

"The Indications for Transfusion," by Dr. Reuben Ottenberg
'Blood Grouping and Blood Matching Technic,' by Dr. Philip Levine

'The Blood Donor Bureau and the Examination of Donors,' by Dr. David C. Bull

"The Accepted Methods of Blood Transfusion," by Dr. Lester J. Unger

'The Use of Universal Group Donors,' by Dr. Arthur F. Coca

The association has just completed an autochrome moving picture on the working of the Blood Donor Bureau, the technic of blood grouping and matching, and the three accepted methods of blood transfusion, the citrate method, the multiple syringe or Lindeman

method, and the syringe-valve or Unger method. This film was prepared at the suggestion of the Maternal and Child Health Division of the United States Department of Labor and is to be used chiefly to educate general practitioners in the various phases of transfusion. The film was shown at the Paris congress by Dr. Lester J. Unger.

CONCLUSION

It is safe to say that the work that has been done by the Blood Transfusion Betterment Association and the recognition which it has received in the city of New York will stimulate the organization of services along the same lines elsewhere. Any city of considerable size with its suburbs or satellite towns can establish a similar organization without great difficulty and with the promise that it will function as usefully as the Blood Transfusion Betterment Association of New York City.

KIRSCHNER TRACTION IN THE TREATMENT OF MAXILLARY FRACTURES

GLENN MAJOR, D.D.S., M.D., PH.D. IN SURG.
PITTSBURGH

Numerous methods and mechanical devices have been perfected for the treatment of fractures of the superior maxilla. This fact implies that each appliance does not readily adapt itself to the treatment of all types of maxillary fracture. As in the case of fractures elsewhere, the position of the fragments must be considered before a satisfactory method of reduction can be selected. Furthermore, under certain conditions perfect apposition of the fragments is demanded.

It is a noteworthy fact that a high percentage of fractures of the upper jaw are complicated by fracture of the skull through the anterior cranial fossa. Most of these fractures are compound, projecting through the nose, and nasal damage of cerebrospinal fluid is usually present. Obviously, the first consideration is the possibility of injury to the brain, due either to laceration or to hemorrhage and the second consideration is the potentiality of intracranial infection in the nature of meningitis, sinus thrombosis or abscess of the brain. The patient should be treated conservatively for at least one week, the treatment being that ordinarily employed for fracture of the skull. In addition the maxilla should be immobilized as completely as is possible with a head-chin bandage, a procedure which is grossly inadequate at best. The nose should be sprayed at frequent intervals with an antiseptic solution, the nature of the solution depending on the preference of the surgeon. At the Western Pennsylvania Hospital, tincture of mercuriolate is employed. The primary principle in the early treatment of fractures of this type is conservatism, with absolutely no manipulation of the fragments. It seems probable that the area surrounding the fracture of the skull is soon walled off by a blood clot, and to manipulate the maxillary fragments in this stage is to reopen the area and thus increase the possibility of intracranial infection.

Another feature demanding attention in the treatment of fractures of the upper jaw is the question of diplopia.

It is amazing the amount of comminution that occurs in the region of the floor of the orbit with no disturbance in normal binocular single vision. This is probably explainable on the basis of an intact suspensory ligament, which may maintain the eye in its normal position despite marked destruction of the floor of the orbit. However, if the fracture is accompanied by injury to the facial attachments of the ligament or by laceration of the ligament itself, diplopia often results. It is then imperative that the fragments be reduced accurately, so that the two eyeballs are brought to the same normal horizontal level. Such a fracture is illustrated in figure 1.

A feature of fracture of the maxilla which is peculiar to this injury is the question of involvement of the maxillary frontal or ethmoidal sinuses. Rarely does a fracture of the maxilla occur in which the fracture line does not involve one of these sinuses. Fortunately, however, marked sinus infection after such an injury is the exception rather than the rule. It is true that the sinuses transilluminate poorly at first, the cloudiness being due to the extravasation of blood into the cavity in question. Only occasionally does the sinus become clinically infected. This complication, when it occurs, is treated as acute sinusitis without fracture.

One other feature of the maxilla which is worthy of note is the tardiness of union of the bone. Usually at the end of from three to five weeks all splints may be removed, but as a general rule several more weeks or sometimes months, must elapse before complete firm union has resulted. In this regard, fractures of the maxilla differ radically from those of the mandible, in which union is usually prompt.

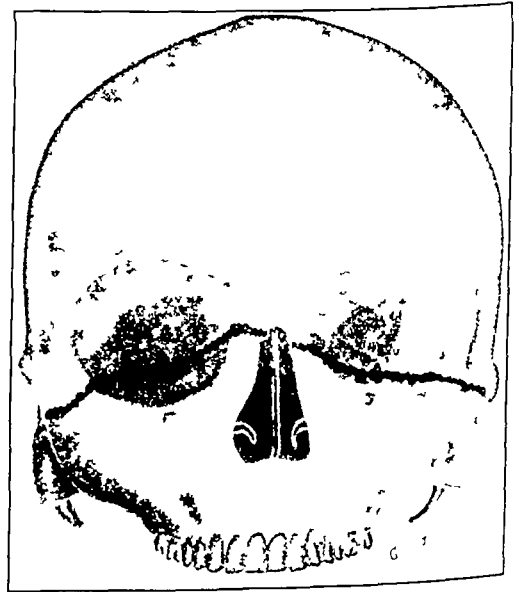

Fig. 1—Comminuted fracture passing through the floor of the orbit.

Another difference between fractures of the maxilla and those of the mandible is the frequency of osteomyelitis at the line of fracture. This complication in the upper jaw is rather uncommon, while in the mandible it occurs in from 5 to 10 per cent of the cases. The explanation of this discrepancy depends on the better blood supply of the maxilla and the fact that when compound fractures of the mandible project into the mouth drainage is inadequate along the fracture line.

In treating fractures of the jaws the occasional surgeon in this field often forgets one obvious fact. The teeth must be brought into occlusion, and the cusps of the teeth should interdigitate in their normal relations. Otherwise the functional result will be poor. When the maxilla or the mandible is fractured, a perfect

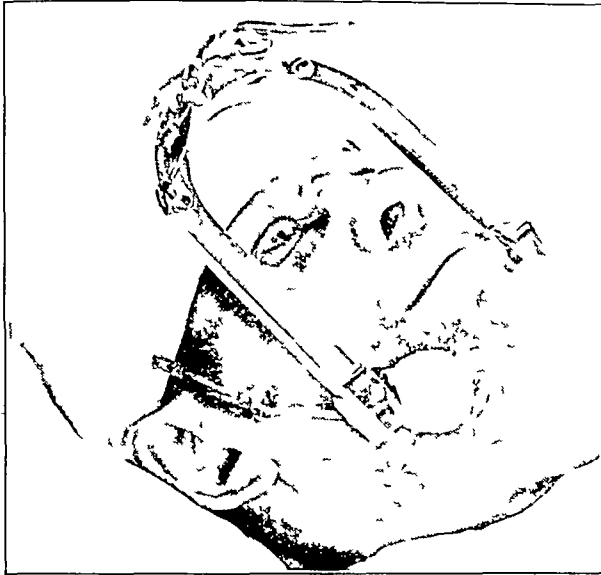

Fig. 2—Rubber band traction for the reduction of fractures of the maxilla

functional result usually implies a perfect anatomic result. Exceptions occur when the mandibular ramus or the neck of the condyle is fractured.

In general, three methods are used at present in the treatment of fractures of the maxilla. First, traction is exerted by rubber bands between a head cast or head cap and lugs brought out at each angle of the mouth, the lugs being soldered to a splint which is wired to the upper teeth. In some cases this method is adequate. However, in such cases there is a marked tendency to depression of the posterior aspect of the maxilla. When this method is used in our clinic my associates and I advocate, in addition to the splint, rubber band traction or wiring between the maxillary and the mandibular teeth, to preserve the interdigitating relation between the two sets.

A second method is simply to use rubber band traction between a head cast or head cap and mole skin applied to the skin or a molded, well padded plaster chin piece. In my hands this procedure has been inadequate, as well as uncomfortable to the patient. If it is used, interdental wiring or interdental rubber band traction is again recommended, to preserve the finer relations between the teeth.

A third method is simple interdental wiring or interdental rubber band traction. In case of an incomplete horizontal fracture of the maxilla this is an adequate procedure. It is particularly well adapted to the treatment of unilateral fractures of the alveolus or vertical fractures.

In our clinic we have occasional cases of fracture of the maxilla in which we experience considerable difficulty in restoring the lower fragment to its original position. Because of the delay of a week or ten days before reduction is attempted, we feel that there is considerable organization of the hemorrhage between

the fragments, which renders complete reduction difficult. The patients often complain bitterly of pain with skin traction and the other methods discussed. As a solution to this problem, it occurred to us that skeletal traction would be valuable. At the present time we are treating these more difficult fractures as follows.

One week after the cerebrospinal hemorrhage has ceased, in the absence of symptoms suggestive of intracranial infection or increased intracranial pressure, a head cast is applied. The method of application is important and is described fully by Ivy and Curtis.¹ A heavy iron wire is incorporated in the cast, conforming to the contour of the head, with a lug emerging from the cast above and anterior to the tragus of each ear. Another smaller wire emerges from the cast in the frontal area. The former wire is used for traction, as discussed later, and the latter is used to attach the spreader to the head cast, as described hereafter.

The mandibular nerve is injected on each side with procaine hydrochloride. After topical anesthesia of the mucous membranes of the upper jaw is secured and this deep nerve of the lower jaw is injected, splints are applied to the labial and the buccal aspects of both the upper and the lower teeth. The splints are wired to three or four teeth on each side above and below with double 26 gage stainless steel wire. Any one of several splints may be used for this purpose, but in our clinic we have used the splint made by the Jelenko Company. This splint is provided with lugs at intervals of about 1 cm, the lugs on the upper splint being directed upward and those on the lower splint being directed downward. The splints are applied at this time so that, after the fracture has been gradually reduced by skeletal traction,

Fig. 3—Apparatus for the reduction of fracture of the maxilla by skeletal traction

rubber bands may be applied between the upper and the lower splint and the finer adjustments made to bring the teeth into their original relations.

Under sterile conditions a Kirschner wire is now inserted into the symphysis of the mandible. No additional anesthesia is required, since the mental nerve has been anesthetized. A small nick is made in the skin and

¹ Ivy, R. H. and Curtis, Lawrence. Fractures of the Jaw. Philadelphia: Lea & Febiger, 1931.

extended down to the outer aspect of the mandible. With a bone drill a hole is started in the mandible at a point one-eighth inch above its inferior border and one-half inch posterior to the symphysis, so that injury of the mental nerve is avoided as well as injury of the apexes of the teeth. After the hole has been started, the Kirschner wire is introduced and is brought out on the opposite side of the mandible at a point corresponding to the point of entrance. This wire lies entirely within the mandible and does not pass through the floor of the mouth, being entirely extra-oral. As the wire emerges a small nick is made in the skin. A spreader is attached and dressings applied to the points of entrance and exit of the wire. The spreader is brought up to the frontal area and attached to the cast wire in that position. Traction is not applied to the spreader itself. S-shaped hooks are applied to the Kirschner wire on each side, and similar hooks are placed on the iron wire incorporated in the head cast in the preauricular areas. A turnbuckle (32 threads to an inch) is inserted between the two S-hooks on each side, and the slack is taken up by turning the turnbuckle. Originally we employed rubber band traction, as shown in figure 2, but we find that more gradual traction can be exerted by the turnbuckles. The patient is then returned to his room. The apparatus is shown in figure 3.

Several days should be consumed in effecting the reduction. The nurse is instructed to turn each turnbuckle one eighth of a revolution every three hours. If the patient complains of pain in the region of the fracture the turning is done more slowly. The desirability of this method lies in the fact that reduction can be accomplished gradually, thereby lessening the chance of further injury to the contents of the anterior cranial fossa and minimizing the tendency to reopen sealed off defects in the anterior fossa. Another prominent feature is the almost complete absence of discomfort. It will be evident that the reduction is effected by force transmitted through the mandibular to the maxillary teeth.

After the reduction has been completed, the wire and the spreader are left in place for three or four days, after which the wire, head cast and spreader are removed and rubber bands are applied between the previously placed upper and lower intra-oral splints. The splints are worn for an additional period of from three to five weeks, depending on conditions, after which they are removed.

In this manner the more difficult fractures can be reduced and excellent anatomic and functional results obtained with a minimum of discomfort. A concomitant fracture of the mandible may occasionally be a contraindication to this method. Ordinarily the method is not applicable in the treatment of edentulous persons. We have not used it in treating such persons with the dentures in place.

SUMMARY

The method described for the gradual reduction of horizontal fractures of the maxilla, based on the principles of skeletal traction and involving a Kirschner wire, is considered valuable for three reasons. It effects gradual and complete reduction of these fractures, and tremendous force may be exerted, if desired, with practically no discomfort to the patient, the apparatus can easily be applied with the patient under local anesthesia, and there is little possibility of additional intracranial injury or infection, because of the gradual reduction.

CHEMOPROPHYLAXIS IN POLIOMYELITIS

THE TECHNIC OF APPLYING CHEMICAL AGENTS TO THE OLFACTORY MUCOSA

LEE SHAHINIAN, MD

J A BACHER, MD

R C McNAUGHT, MD

AND

R R NEWELL, MD

SAN FRANCISCO

The observations of Armstrong and Harrison,¹ those of Sabin, Olitsky and Cox² and, especially, those of Schultz and Gebhardt³ seem to show conclusively that certain chemical agents carefully applied to the olfactory mucosa of monkeys afford considerable protection against infection by subsequent intranasal instillation of poliomyelitis virus. The essential observations which have been made up to the present were summarized in a recent article by Schultz and Gebhardt⁴ and therefore

do not need to be repeated here.

This evidence, that a chemical agent such as 1 per cent zinc sulfate confers on monkeys a high degree of resistance against poliomyelitis virus for at least one month after treatment, suggests that such a prophylactic measure may deserve a trial in human beings during periods when poliomyelitis is prevalent. We have concerned ourselves primarily with devising a method of applying the prophylactic treatments that can be easily and accurately used by the physician with a minimum of discomfort and risk of injury to the patient.

tum to insure accurate placement of the solution to the olfactory area. This procedure is difficult and admittedly not free from danger.

2 Postural Methods—These methods depend on the localization of the prophylactic fluid in the nasal vault by gravity. Peet and his associates⁶ dismissed the routine instillation of the fluid into the nose by dropper as unsatisfactory. They quoted no experimental evi-

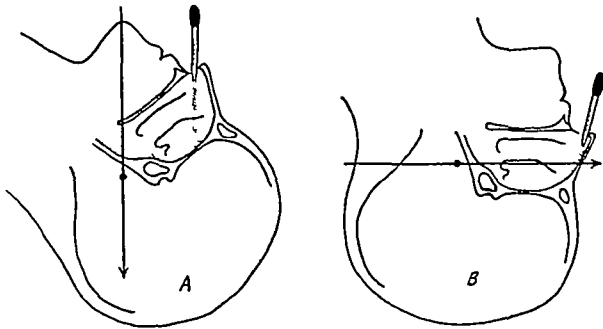

Fig 2—A head inverted so that the chin and the auditory meatus are in the same vertical plane (Proetz position). Fluid dropped into the nose primarily seeks the pocket formed by the cribriform plate and the face of the sphenoid bone. The cribriform plate is approximately 40 degrees from horizontal. B head completely inverted so that a line between the infra-orbital ridge and the external auditory meatus is horizontal. The cribriform plate is approximately horizontal. Fluid placed in the olfactory groove at the limen nasi accurately reaches and fills the inverted common nasal meatus.

dence against this practice except to state that radiopaque material did not regularly reach the olfactory area when sprayed into the nose with an ordinary atomizer, the patient being held in the Proetz inverted position.

A recent paper by Pentecost⁶ advised the direct placement of the prophylactic fluid in the olfactory area with an olive tip ureteral catheter inserted between the middle turbinate and the septum, with the patient's head in the Proetz position ("head is inverted so that the chin and external auditory meatus are in the same vertical plane"). His experiments on human volunteers consisted of thus placing a solution of local anesthetic and then testing for loss of sensation in the olfactory area. We used a variation of this method in our basic studies but believe the position to be incorrect and the procedure more difficult than necessary.

ANATOMIC CONSIDERATIONS

The olfactory area covers nearly the whole of the superior turbinate, a small contiguous portion of the middle turbinate and the area of the septum directly opposite these surfaces (fig 1). The olfactory surfaces enclose approximately the upper third of the common nasal meatus. Hence, if this fissure-like space is filled to sufficient height with a lake of fluid, the olfactory membrane will be completely immersed.

The base line of the skull (Reid's base line) extends from the infra-orbital ridge through the external auditory meatus. It is approximately parallel to the cribriform plate, which forms the bony roof of the nose. When the head is completely inverted, with the base line horizontal (figs 2 B and 3), the cribriform plate becomes the horizontal floor of a narrow trough, the inverted common nasal meatus.

When the chin and ear line is vertical the cribriform plate is tipped at an angle of 40 degrees from horizontal.

Proetz⁸ originally described this position for use in the displacement method of filling the accessory nasal sinuses, for which purpose it is excellent. It is unsuited however, for use in applying solutions accurately to the olfactory area. When the head is in this position, the pocket formed by the cribriform plate of the ethmoid process and the face of the sphenoid bone constitutes the angular floor of the nasal chamber (figure 2 A). Hence, limited quantities of fluid dropped into the nose will primarily seek this lowest level and, secondarily reach the level of the olfactory area only if more fluid is added. This additional fluid may be insufficient to cover the olfactory area if the normal sinus ostia are sufficiently patent, as they frequently are, to allow the fluid to escape into the sphenoid and posterior ethmoid sinuses.

The olfactory sulcus is a narrow cleftlike space on the inner surface of the dorsum of the nose, formed by the arched confluence of the septum and the lateral nasal wall. It leads from the nasal vestibule to the roof of the common nasal meatus. Common aberrations in nasal structure do not seem to destroy the integrity of this groove along the vault of the nose, since it is above the attachment of the middle turbinate to the lateral nasal wall and is therefore relatively unaffected by abnormalities of turbinate and septum.

PROCEDURE ADVISED

We have roentgen and clinical evidence to show that when the head is completely inverted, with the base line horizontal (figs 2 B and 3), limited quantities of fluid introduced slowly into the olfactory sulcus at the limen nasi will flow along the groove and accurately fill the inverted common nasal meatus in a selective manner, to a height usually sufficient to immerse most of the estimated olfactory area. This method was found to be as efficient as the more difficult procedure of direct placement of fluid to the olfactory area with

Fig 3—Proper position and technique for applying prophylactic solution to the olfactory area. The base line of the skull is horizontal.

a delicate ureteral catheter placed between the middle turbinate and the septum.

Previous shrinkage of the nose was found unnecessary. All solutions placed in the nose were found to be better tolerated when previously warmed to body temperature in a water bath. Ordinary medicine droppers, previously calibrated for volume are used. With a speculum spreading the anterior nares, the tip

of the dropper is inserted approximately 0.5 cm into the nares, at the anterior angle of the nose, without touching the sensitive mucous membrane walls. The fluid is introduced slowly and steadily, drop by drop. The patient is kept in the inverted position one minute after the last drop has entered.

At the end of treatment, the solution may be emptied by the route of entry by having the patient turn over

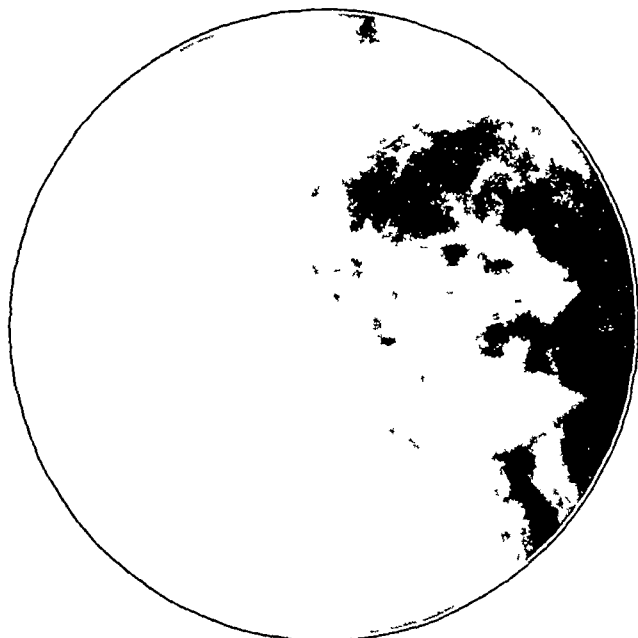

Fig. 4—Lateral view of the skull taken with the subject who was 8 years old in a completely inverted position after 0.4 cc of solution had been placed in each nares. The lower level of the column of radiopaque fluid is contiguous with the horizontal cribriform plate and curves anteriorly on the dorsum of the nose. The upper level is parallel to the cribriform plate (compare with figure 2 B).

into the prone position, lift his head and sniff outward. This procedure prevents unpleasant effects on the throat due to the patient's swallowing the solution.

CLINICAL EXPERIMENTS

Our studies indicate that the physical action of a lake of fluid in the olfactory area may be more efficacious than the action of a spray. In several cases 0.25 cc of physiologic solution of sodium chloride was introduced into the olfactory groove by the method described. It was found that this small amount of solution may be largely removed after one minute if the head is kept in the inverted position. To accomplish this, we introduced a delicate No. 6 (2 mm) ureteral catheter, on the end of a No. 22 needle, directly between the middle turbinate and the septum into the vault of the common nasal meatus. Gentle suction with this device recovered the greater portion of the fluid, hazy with shreds of mucus. This indicates that the lake of fluid probably loosens the mucous protective layer over the olfactory mucosa.

ROENTGEN STUDIES

Colloidal thorium dioxide (thorium dioxide sol, thorotrast) was used. The physical properties of this solution and those of a solution of 1 per cent zinc sulfate were found to differ not enough to interfere with experimental analogy. The colloidal thorium dioxide does not cause any discomfort in the nose, and children readily permitted experiments using it. It is easily blown out of the nose after the procedure is completed.

Studies were made on thirty subjects, twelve of whom were adults, the rest were children between the

ages of 2 and 14 years. Repeated experiments were made in order to evaluate different positions, methods of application and the quantity of fluid necessary. At first the solution was placed directly to the olfactory area with a fine ureteral catheter and with the patient's head completely inverted, the base line of the skull being kept horizontal. Anteroposterior and lateral films taken after thirty seconds demonstrated that the radiopaque fluid filled the common meatus to a desired height. The result obtained by this method was satisfactory and was thereafter used as a standard in gauging the results obtained by simpler techniques of application. Of these, the simple method described in the paragraph on procedure was shown to give accurate selective filling of the inverted common meatus in all of the subjects.

Trials using the position in which the chin and ear line is vertical with seven children between the ages of 3 and 14 convinced us of the likelihood of filling by this technic the middle meatus and the sinus cell instead of the vault of the common meatus. In three cases part of the fluid was in the vault of the common meatus, but the fluid level resembled that illustrated in figure 2 A. As the completely inverted position is easy to obtain and does not lead to failures, we propose to use it and no other.

In the final trials small quantities of the radiopaque solution were placed in the nose by the method described in the section on procedure. Lateral films of the fluid column in position in the olfactory area show the lower, or cribriform, level to be quite straight, but the upper, or nasal, level is wavy because of capillarity and varia-

Fig. 5—The same subject as in figure 4. Posterior projection of the skull in the completely inverted position shows the accurate and selective filling of the inverted common nasal meatus.

tions of width (fig. 4). The posterior projection shows the maximum height and width of the fluid column and is useful in demonstrating the selective manner by which the fluid attains the proper position (fig. 5).

Each adult subject had a clinical examination of the nasal vault before the roentgen studies. Various grades of deviation of the septum and enlargement of the middle turbinate were noted. Yet in fifteen trials

with twelve adults, 0.25 cc of the solution filled the inverted common nasal meatus to a satisfactory level. Preliminary shrinkage of the nasal mucosa was found unnecessary. The depth of filling averaged 14 mm, in only one case was the height less than 11 mm. The maximum widths of the fluid columns averaged 1.5 mm (from 0.5 to 3 mm), exclusive of one much curved column and one measuring 4 mm in one place and 1 mm in another. In one third of the adults 0.25 cc gave a little spilling over into the middle meatus and the sinus cells.

We found the method equally successful in the treatment of children. The superior portion of the common meatus is wider in younger children. This made it necessary to use a larger quantity of fluid to accomplish a desirable height of filling (approximately 0.4 to 0.5 cc). Clinical examination showed structural deformities to be uncommon in children under 10 years of age. For these reasons the fluid column was easier to demonstrate in the lateral roentgenograms. Precise measurements of the volume necessary to cover the required area showed some variability. For instance, the meatus of one 8 year old child had a maximum width of 5 mm and filled to only 7 mm with 0.25 cc and then up to 19 mm when 0.25 cc was added, yet there was no spilling over. A younger child, 20 months old, with a maximum width of 4 mm, filled to 18 mm with 0.5 cc.

It is therefore evident that if one uses a volume so small that no fluid overflows in any of the subjects then the meatus of some will fill to a height of less than 1 cm, which may let some of the olfactory membrane escape. To get sufficient height of filling in nearly all children, one will have to use about 0.5 cc and let a portion spill over into the middle meatus in most of them.

CONCLUSIONS

1 The success of this simple, safe, yet accurate method of applying solutions to the human olfactory area depends primarily on the complete inversion of the head, with the base line of the skull horizontal, and the slow introduction of the fluid along the inner surface of the dorsum of the nose at the vestibular margin.

2 The approximate quantity of fluid necessary to immerse adequately the olfactory membrane by this method has been determined. Five-tenths cc for children under 10 years, 0.4 cc for those between 10 and 14 and 0.25 cc for adults is probably sufficient, a portion of the fluid will overflow in some of the subjects. We have stressed the quantity of fluid to be used because we feel that distress after treatment with chemical agents may thus be minimized.

Urban Civilization and Physical Deteriorization —

With the development of urban civilization and industry physical deterioration becomes appallingly common. All sorts of pathologies multiply, enlarged communications bring new and virulent infections, every sort of physical abnormality is increasingly prevalent. The biological status of man seems to decline as his culture accelerates. Medical science intervenes and becomes efficacious in the reduction of suffering and the prolongation of life but, unfortunately also in the preservation of the malformed, the chronically diseased and the biologically inferior—Hooton E. A. Apes Men and Morons New York G. P. Putnam's Sons, 1937, page 293.

NONOPERATIVE MANAGEMENT OF REMAINING COMMON DUCT STONES

R. RUSSELL BEST, M.D.

AND

N. FREDERICK HICKEN, M.D.

OMAHA

During the last few years we have taken many immediate cholangiograms at the operating table and have adopted the rule of making delayed studies in all cases of common duct drainage or biliary fistula. These series of follow-up cholangiograms have added measurably to our knowledge of the pathologic physiology of the extrahepatic biliary tract. In our earlier investigations we used an iodized oil as the contrast medium but have since come to believe that the heavy oil obscures the smaller stones. Colloidal thorium dioxide (thorium dioxide sol, thorotrast) is an excellent radiopaque solution, but until certain controversies about its potential dangers are settled we have discontinued its use. From our own experience, dating

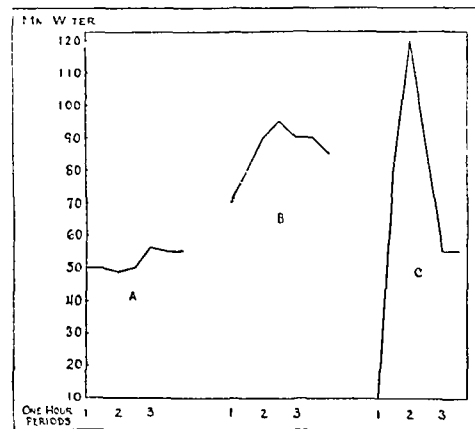

Fig. 1—These measurements of intraductal pressure in a case with T tube in the common duct contrast the height of pressure in control periods with the pressure following administration of dehydrocholic acid.

back three years, we have no regrets and do not believe that colloidal thorium dioxide carries any hazard. We have used a 48 per cent solution of hippuran almost as a matter of routine for the past eighteen months, with gratifying results.

Much to our surprise, we have not infrequently found delayed cholangiograms to reveal stones or foreign bodies such as blood clots, organized debris or inspissated bile in common ducts which were thoroughly explored by palpation, probing, scooping, irrigation and suction at the time of operation. Thus it has been forcibly brought to our attention that these foreign bodies may be left within the duct or may be washed down from the liver. In the past we have not been sufficiently cognizant of the series of events which takes place in the common duct after surgical treatment of the biliary tract. It can be fully appreciated only by those who have determined the postoperative status of the common duct through cholangiography. With this situation in mind, and fully aware of the mortality attending secondary attacks on the biliary tract, we have attempted to dislodge some of these foreign bodies by various nonoperative measures.

From the departments of surgery and anatomy, University of Nebraska College of Medicine.

The first problem is to provide a free exit at the lower end of the common duct through which the foreign elements may pass into the duodenum. The sphincter of Oddi guards this portion of the duct and is probably associated with a pseudosphincter action of the muscular fibers of the duodenal wall itself. If not in an absolute state of relaxation this sphincter mechanism

Fig. 2 (case 1)—This cholangiogram taken some weeks after operation reveals the rounded margin of a stone blocking the lower end of the common duct and the pancreatic duct. Repetition of the injection and a roentgenogram confirmed its presence.

may prevent the egress of the contents of the common duct. It is often found to be unrelaxed and not infrequently is definitely spastic. This motor dysfunction of the lower end of the common duct has been mentioned often in interesting articles by Westphal,¹ Newman,² Ivy and Sandblom,³ and various others. In 1935 we demonstrated by means of cholangiograms that an unrelaxed or spastic state of

the sphincter area could exist in human beings.⁴ In 1936 Walters and his group⁵ reported their experiments on common duct pressure as affected by spasm of the sphincter. We have also studied the effects of various drugs on this phenomenon and at the annual session of the American Medical Association in 1936 presented a paper⁶ on cholangiography and biliary dyskinesia in which the use of glyceryl trinitrate was proposed. Cholangiograms proved that in many instances the sphincter of Oddi immediately relaxed after $\frac{1}{100}$ gram (0.0006 Gm.) of glyceryl trinitrate was placed beneath the tongue, for the contrast solution readily entered the duodenum.

In the course of these investigations it was noticed that morphine did not produce relaxation and that atropine was not constant in its effects. The reports of Walters and his group on biliary pressure substantiate this observation. They also found that amyl nitrite and glyceryl trinitrate decrease biliary pressure by relaxing the sphincter of Oddi and that morphine causes increased pressure through contraction of the sphincter muscle. Even more recently, Doubilet and Colp⁷ have corroborated the effects of glyceryl trinitrate and morphine by further pressure studies. In addition, they have shown that atropine may lessen the tension in the irritable area around the sphincter, which observation concurs with our cholangiographic data.

We have observed, with the aid of cholangiograms the magnesium sulfate on the duodenal side of the choledochal sphincter assists the contents of the common duct to pass more freely into the duodenum. This seems to be true of olive oil as well. We have also reported on the apparent soothing or relaxing effect of warm olive oil or iodized oil when applied to the choledochal side of the sphincter of Oddi through a T tube or fistula.

Since the sphincter may or may not be spastic in the event of a remaining stone in the common duct, the second step in dislodging the foreign body is increasing the pressure behind it. This is easily accomplished by injecting saline solution, olive oil or iodized oil through the drainage tube or fistula if the foreign body is below their level. If, however, these smaller particles are lodged above the opening of the tube or fistula, they may be forced higher into the hepatic duct or into the larger biliary radicles within the liver. Again after these higher stones are once dislodged, they may find their way down to the lower end of the common duct. It is also conceivable that increasing the flow of bile by stimulating its formation will augment the intraductal pressure. Neubauer⁸ in 1925 determined by experiments on animals and human beings that sodium dehydrocholate, the sodium salt of dehydrocholic acid, increased the secretion of bile. We have therefore been experimenting with pressure changes as affected by dehydrocholic acid, and although we are not reporting in detail in this paper, we are able to say that the flow of bile and the intraductal pressure are heightened after administration of either decholin or procholol, the commercial products of dehydrocholic acid (fig. 1). This added pressure is of greatest value when

the foreign body is below the inlet of the T tube, catheter or fistula in the common duct as it tends to force the impediment through the sphincter during some momentary period of relaxation. The normal intraductal pressure varies with different cases but the usual pressure is somewhere between 50 and 125 mm. of water⁹ in postoperative cases. The resistance of the sphincter or breaking point is 150 mm. Doubilet and Colp⁷ have

Fig. 3 (case 1)—The described management was instituted but only after repeated attempts over a two-month period was a plate obtained which showed the stone had disappeared. Evidently swelling and edema had to subside before dislodgement could be accomplished. Repeated check-ups confirmed the disappearance of the stone. The pancreatic duct is still visible.

only recently reported cases showing variations in the resistance of the sphincter and the effects of different drugs on this area. These variations were most con-

spicuous in our early cholangiographic studies,¹⁰ ranging from complete relaxation to complete spastic occlusion and even resulting, in one instance in cholitic stools over a period of weeks. Edema or inflammation in this region will tend to narrow the outlet further.

The following case illustrates the possibility of dislodging a stone from the common duct by the aforementioned method, after the edema in the sphincter area has subsided.

History.—O. M., a man aged 35, had recurrent attacks of indigestion for sixteen months, accompanied by pain in the upper part of the abdomen, nausea and vomiting. Morphine was required for relief, and on one occasion he became slightly jaundiced. The week before he entered the hospital he had a severe pain in the upper part of the abdomen which required several injections for relief and within three days he became icteric. When examined the patient was very apprehensive, definitely jaundiced and moderately tender over the gallbladder. His icteric index was 75, the van den Bergh direct delayed reaction was moderately positive, the stools contained bile, the temperature was 99.8 F and the leukocyte count was 10,600. By conservative management the icteric index was brought down to 35 and after five days of observation and preparation

had continued attacks of chills, fever, distress in the upper part of the abdomen and intermittent jaundice. The sinus tract would close, only to reopen and drain pus and bile. This process recurred a number of times.

About ten weeks after the first operation another cholangiogram made by injecting 20 cc of hippuran solution into the fistulous tract, revealed two stones in the common duct which had not been visible on the previous plates. Operation was advised.

Second Operation.—Several days later an attempt was made to locate and remove the stones from the enlarged common duct. The head of the pancreas was also larger than normal, hard and irregular, as is consistent with marked chronic pancreatitis or new growth. There was a pronounced inflammation around the common duct and the duodenum. The duct was explored as thoroughly as possible in the presence of this inflammatory reaction, finger, probe, scoop, irrigation and suction being used, but no stone could be located or dislodged. By this time the patient's condition was unsatisfactory, contraindicating a transduodenal attack. Therefore a T tube was hurriedly placed in the common duct and the abdomen was closed.

Because of digestion of the tissues around the wound a cholangiogram was not taken for three weeks at which time

Fig. 4 (case 2).—This cholangiogram was made one week after operation. Multiple round filling defects are visible in the common duct. The duct is still patent as the hippuran solution can be seen in the duodenum.

Fig. 5 (case 2).—After the described treatment ten stones were recovered from the stools. The cholangiogram reveals one more stone remaining at the lower end of the common duct.

Fig. 6 (case 2).—After another course of treatment this stone was recovered from the stool and the cholangiogram reveals no more stones in the common duct.

the patient was operated on the diagnosis was cholecystitis, cholelithiasis and stone in the common duct.

First Operation.—With the patient under spinal anesthesia the gallbladder, thick walled, definitely inflamed and adherent to surrounding structures was removed. The common duct was about twice normal size and was angulated at its junction with the cystic duct by inflammatory adhesions. These were freed and the duct was opened. Thorough palpation, probing, scooping and washing revealed no stone. The head of the pancreas was thickened and harder than normal. A T tube was placed in the common duct for drainage.

On the sixth postoperative day a cholangiogram was made by injecting 20 cc of hippuran solution into the common duct through the T tube. No stone was visible, but the sphincter was contracted. This spasm was relaxed by dissolving $\frac{1}{100}$ gram of glyceryl trimurate beneath the patient's tongue. The T tube was removed on the tenth postoperative day after a check up cholangiogram which again revealed some sphincterismus but no stone. The patient was discharged from the hospital a few days later to the care of his local doctor with a remaining biliary fistula. During the next two months he

the picture was a little suggestive of a single stone remaining in the ampulla. A recheck four weeks later definitely revealed a stone at the lower end of the common duct (fig. 2). The entire length of the pancreatic duct was easily seen on this plate.

A three day regimen with dehydrocholic acid and antispasmodic drugs was instituted and repeated every ten days. In the intervals the duct was washed out on alternate days with sterile olive oil or Iodoine. With each oil irrigation, $\frac{1}{100}$ gram of glyceryl trimurate was placed beneath the tongue.

A follow-up cholangiogram, one month after institution of this treatment showed the stone still present, but the dye entered the duodenum more readily. After a second month of treatment no evidence of a filling defect could be found at the lower end of the common duct (fig. 3).

The T tube was then clamped off, except at night for another thirty days when a recheck showed no indication of a stone in the common duct.

This confirmation warranted removal of the T tube and now, eight months later the patient weighs more than he ever did, feels perfectly well and is back at his regular duties.

Evidently, in this case drainage of the common duct and time were needed for the subsidence of the pancreatic inflammation and then proper measures caused the stone to be dislodged.

10. Hicken, A. F., Best, J. R., and Hunt, H. B. Cholangiography. Visualization of the Gallbladder and Bile Ducts During and After Operation. *Ann. Surg.* 103: 210-229 (Feb.) 1936. Best and Hicken footnote 4 and 6.

We have come to believe that stones are present in the larger biliary ducts of the liver more frequently than is recorded. More detailed examination of the liver at autopsy would support this statement, for during the last year we have demonstrated such stones in two instances but only after thorough search through the liver. One patient had a postoperative stone in the common duct and also unrecognized carcinoma of the kidney. The other patient was one on whom a routine autopsy was performed after he had died of cardiovascular disease.

The following case is presented because it more definitely substantiates the release of intrahepatic stones into the common duct. These stones were detected in the common duct by cholangiograms and then were successfully dislodged by the regimen described.

CASE 2—History—For five years R. F. C., a married woman, aged 28, had been having attacks of nausea and vomiting which were associated with loss of appetite, slight distress in the upper part of the abdomen but no true pain. Removal of her appendix did not alleviate the symptoms but rather the attacks became more frequent. Three days before entering the hospital she was suddenly seized with a sharp pain in the right upper quadrant, which radiated to the right scapular region. The paroxysm subsided after the administration of morphine. She presented no history of jaundice but

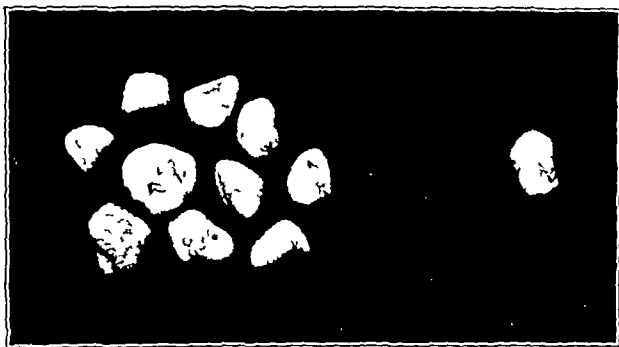

Fig. 1 (case 2)—The group of ten stones were recovered from the stool after the first course of treatment. The single stone was recovered after the second course.

for some years she had noticed a sensation of pressure immediately after meals which would last for half an hour and was not relieved by sodium bicarbonate.

Examination revealed a well developed young woman in no apparent distress. The only positive evidence was slight tenderness over the gallbladder. No rigidity and no definite masses were palpable. Her temperature and pulse were normal. The white blood count was 10,400 and the icteric index 10.

Operation—The large distended gallbladder was adherent to the duodenum. The common duct appeared two or three times normal size, with no stones palpable in its lumen. After the gallbladder was removed it was incised and found to contain about 200 pea-size stones. The common duct was opened through the stump of the cystic duct but palpation, probing, scooping, suction and irrigation revealed no stones. A catheter was then placed in the common duct and the abdomen was closed.

One week after operation a cholangiogram made with 20 cc of hippuran solution revealed multiple pea-size stones in the common duct (fig. 4). A cholangiogram made several days later gave the same picture.

Postoperative Measures—As soon as the patient's condition warranted it, the previously described therapeutic measures were begun. After the first course of treatment ten stones were recovered from the stools. The cholangiogram was repeated and one stone was found remaining in the ampulla

(fig. 5). A second course of treatment resulted in passage of the eleventh stone (fig. 6). Two subsequent check-ups gave negative results (fig. 7). The fistula soon closed, and eight months later, the patient feels perfectly well.

We have been able to depict apparent foreign bodies in two other common ducts by postoperative cholangiograms, but these defects were inconstant in appearance as well as irregular in shape. It is highly possible that they were small blood clots or lumps of inspissated bile which were later dislodged. In any event, they disappeared under the described treatment. In a recent case, although no stone could be palpated, the postoperative cholangiogram revealed a large stone within the common duct. Repeated efforts to dislodge it have been ineffectual, and ether has also failed to break it up. Another operation is to be advised.

SUGGESTED TECHNIC FOR REMOVAL OF REMAINING COMMON DUCT STONES

When a stone is located in the common duct by delayed cholangiography, the following three day regimen is begun. On the first day a $\frac{1}{100}$ gram tablet of glyceryl trinitrate is placed under the tongue three times during the day, on the second, $\frac{1}{100}$ gram of atropine is given either by mouth or hypodermically three times, and on the third the administration of glyceryl trinitrate is repeated. Each morning the patient is given 2 drachms (8 Gm.) or more of magnesium sulfate in warm water and each evening at bedtime one ounce (30 cc.) of olive oil (preferably) or thick cream. The common duct is gently irrigated once a day through the T tube, catheter or fistula, with warm physiologic solution of sodium chloride, and after as much of this as possible is removed by syringe or by permitting the tube to drain for five minutes from 10 to 30 cc of warm sterile olive oil or lipectine is instilled into the common duct. If the patient does not complain of distress, the tube should be clamped off during this course of treatment except for a thirty minute period after each instillation. In order to maintain an increased intraductal pressure, three or four tablets of decholin or procholone are given four times a day.

This treatment may be repeated after a few days rest and, as in the first case reported, it may be repeated as many as ten times over a period of two months. It may prove rather debilitating at times, and care must be taken not to exhaust the patient.

The question arises as to the indications for this form of treatment when no fistula or arrangement with a catheter exists. If obstruction is complete, there may be danger of hastening hepatic destruction by increasing the biliary pressure. In several cases in which obstruction has not been complete, we have ventured to use the treatment, omitting the irrigations, with no evident harmful effects and with definite improvement or complete alleviation of the biliary condition. We have recovered no stones from the stools as yet in such instances, but the patient's search for stones at home is not so exacting. One should always be aware of the potential danger in such treatment, however, and until further investigative studies have been made the dehydrocholic acid products should be cautiously prescribed when there is any degree of jaundice with supposition of stone in the common duct. If the jaundice is marked, with acholic stools, great damage might be done to the liver, and dehydrocholic acid should definitely not be prescribed. However, in all

cases following cholecystectomy in which jaundice does not exist, we now place the patient on the described three day regimen about two weeks after operation in an effort to flush the biliary system thoroughly and remove small stones, mucous plugs, inspissated bile and organized debris, thus lessening the incidence of postcholecystectomy difficulties. This particular regimen is now being used in the nonsurgical management of routine biliary tract disease, exclusive of jaundice.

ADIPOSIS DOLOROSA (DERCUM'S DISEASE)

TREATMENT OF THE ASTHENIC PHASE WITH
PROSTIGMINE AND AMINOACETIC ACID

MICHAEL G WOHL MD

AND

NATHAN PASTOR, MD

PHILADELPHIA

If one is to judge from the number of cases reported in the literature, adiposis dolorosa is a rather rare disease. Approximately 250 cases have been described in the world's literature since the original report of the condition by Dercum in 1888. It would seem that the infrequent occurrence of the disease is more apparent than real. Many cases are unrecognized as such and masquerade as endocrine obesity associated with arthritis or menopausal psychosis. Moreover, there has been a tendency in recent years, particularly on the continent to deny the existence of Dercum's disease as a clinical entity. From a critical review of the literature and our studies of the cases to be described here, we are inclined with Laroche¹ to look on it as a syndrome rather than as a disease per se.

The four cardinal signs of Dercum's syndrome are (1) adiposity, (2) asthenia, (3) pain and (4) psychic disturbances. The asthenia is usually out of proportion to all physical activities. The least amount of effort to which the patient has been accustomed fatigues him readily. Sooner or later the asthenia becomes so pronounced as totally to incapacitate the patient. This symptom overshadowed all other complaints by our patients and taxed our therapeutic resources. The other signs of Dercum's disease will receive due consideration in the discussion of the cases. In this presentation we are reporting three cases in which the asthenia was an outstanding feature. This symptom of the disease was combated successfully by the oral use of aminoacetic acid and prostigmine ammonium biomide. To our knowledge this therapeutic regimen was never before employed in Dercum's disease.

REPORT OF CASES

CASE 1—Mrs. B. H., aged 60, white, admitted to the Endocrine Clinic of Temple University Hospital March 17, 1936, complained of pains in both legs, extreme weakness and frequent crying spells without any apparent reason. She gave a history of progressive gain in weight, her highest weight having been 230 pounds (104 Kg.) two years previously. The patient is married and has two children, both living and well. She was not a heavy eater and had no excessive desire for

sweets or fluids. The past history was irrelevant except that in 1934 she was treated in another institution for hypopituitarism.

On examination she was found to be very nervous and depressed, her skin was dry and of a rather pasty color. There was a universal distribution of fat with a predominance over the hips, thighs and abdomen. The arms and legs were thin. There were pads of fat around the metatarsal bones of each foot. There were encapsulated masses of fat on the thighs and hips. These masses were painful on pressure. Physical examination of the chest was negative and the lungs were clear, there was no evidence of heart disease. The blood pressure in millimeters of mercury was 120 systolic and 80 diastolic. The abdomen was pendulous, there were several fatty tender nodules in the abdominal wall. The edge of the liver was not palpable. The spleen was not enlarged. The tendon reflexes were exaggerated. The visual fields were normal, the fundi were not clearly visualized, bilateral immature cataracts were found. The only abnormal laboratory finding was a basal metabolic rate of minus 25 per cent with a blood cholesterol of 138 mg. per hundred cubic centimeters. The sugar tolerance curve was within normal range. The blood calcium content was 11 mg. per hundred cubic centimeters, the blood phosphorus 4 mg. Urinalysis on two occasions revealed no chemical or microscopic abnormalities. The specific gravity varied from 1.006 to 1.013. The blood count showed hemoglobin 75 per cent (Dare), red blood cells 4,410,000, white blood cells

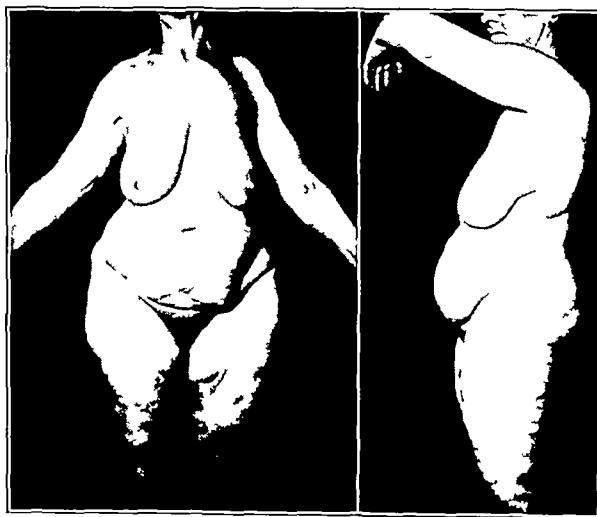

Fig. 1 (case 1)—Adiposis dolorosa. Note lumpy, encapsulated masses of fat on thighs and abdomen, forming an overhanging apron of fat. The upper half of the body is relatively thin (after weight loss of 10 Kg.).

6,000, color index 0.85 and normal erythrocytes. X-ray examination of the skull showed a normal sella turcica. X-ray examination of the chest showed no persistent thymus.

Treatment consisted of a diet with 70 Gm. of protein, 100 Gm. of carbohydrates and 75 Gm. of fat. Because of the question of hypothyroidism as the cause of her condition, she was placed on desiccated thyroid, 1½ grains (0.1 Gm.) daily. In the course of seven months she lost 22 pounds (10 Kg.). The basal metabolic rate October 29 was minus 10 per cent. Her weakness and nervousness persisted. In view of the fact that the blood picture was still that of hypochromic anemia, she was given iron sulfate 15 grains (1 Gm.) daily. The blood picture improved but the patient still continued to complain of weakness, nervousness and depression. The weakness was so distressing that she was forced to stay in bed until midday each day. The least physical effort fatigued her. The tenderness of the lipomatous nodules persisted and nervousness and irritability increased.

Because of the extreme muscle weakness it was thought that there was also a component of myasthenia gravis. The reaction of the sternocleidomastoid muscle to the taradic cur-

From the Department of Medicine, Temple University School of Medicine.

These studies were made possible by the cooperation and aid extended by the various members of the medical staff of Temple University Hospital. L. Laroche, Guy, *Adipose douloureuse et maladie de Dercum*. *Ann. de med.* 23: 445-453 (May) 1928.

rent stimulation by Dr G E Farrar Jr was as follows: Faradic stimulation of the sternocleidomastoid muscle, at the rate of about 25 muscle contractions per minute, showed weakening at 50 contractions. After 0.5 cc of 1:2,000 solution of prostigmine intramuscularly, muscle contractions weakened at 450 contractions. The extensor indicis proprius muscle was exhausted at 50 contractions. After 1 cc of prostigmine intramuscularly, the response was as follows: ten minutes, 250 contractions without fatigue; one hour, two hours, three hours, 300 contractions without fatigue. The patient was given 45 mg of prostigmine daily by mouth. For six weeks she did fairly well. She returned to the clinic after she recovered from an infection of the upper respiratory tract which lasted five days. The weakness and nervousness recurred. Prostigmine was continued for ten days. The benefit from it was not as great as when it was first given. The urine was examined for creatine and showed 70 mg in twenty-four hours on her usual mixed diet. Prostigmine was combined with

aminoacetic acid 15 Gm daily. In the following three months there was a distinct improvement. The urine showed 86 mg of creatine in twenty-four hours. She felt considerably stronger, her nervousness decreased and she was able to carry on her routine daily household work. She is well maintained on aminoacetic acid and prostigmine orally. The urine after four months of combined therapy showed 130 mg of creatine.

CASE 2—Mrs E Z, aged 49, white, admitted to Temple University Hospital April 21, 1937, complained of generalized body pains; they were worse in the legs and knees. The pains were especially severe over masses of subcutaneous 'knots'. The pains had been of several years' duration and had grown

Fig. 2 (case 2)—Illustrating generalized diffuse form of Dermum's disease.

worse in the last few months. She also suffered from weakness and hot flashes, periods of depression and unexplained crying. She had put on considerable weight in the last few years, having reached her admission weight of 226 pounds (102.5 Kg). Her past history was irrelevant except that she underwent a pelvic operation in 1923. This was followed by a decreased menstrual flow and six years later, vasomotor symptoms developed, namely, hot flashes and sweats. Pains in the legs and the arms and in 'lumpy' areas of the body came on about this time. Extreme weakness had appeared in the last two years so that the patient spent a great deal of time in bed.

The patient was well oriented, easily excitable, nervous and obese. The obesity was universal in distribution but predominated over the abdomen, thighs, buttocks and arms. The face was florid, the mammae were pendulous and the skin of the body was of fine texture, warm and moist and showed prominent dermatographism. There were subcutaneous masses of fat, varying in size from an English walnut to an orange, well distributed over the abdomen, chest and arms; they were tender to pressure. The pubic and axillary hair was scanty.

There were varicosities on both legs as well as fatty nodules smaller than those found on the arms. The nodules were tender to touch. There was also marked tenderness about the knees and especially in the popliteal spaces which were padded with collections of fatty masses. Examination of the heart showed a transverse widening with distant sounds. No murmurs were heard and no arrhythmia was found. The aorta was widened, the aortic second sound was accentuated and roughened. The blood pressure was 170 systolic, 110 diastolic, and the pulse rate was 84. The electrocardiogram showed normal sinus rhythm. The lungs were emphysematous. The abdominal viscera could not be palpated because of the pendulous abdomen. Polyneuritis was excluded by Dr S F Gilpin Jr. The examination of the eyes by Dr W J Lill showed slight attenuation of retinal vessels, the visual field was normal.

The various laboratory studies were as follows: hemoglobin 85 per cent (Dare), red blood cells numbered 4,670,000, white blood cells 12,300, polymorphonuclear leukocytes 85 per cent, lymphocytes 15 per cent. There were no abnormal red cells. Urinalysis revealed acidity, specific gravity 1.019, sugar and albumin negative, occult blood negative, microscopic examination negative. Blood chemistry revealed serum calcium 9.9 mg per hundred cubic centimeters of blood, phosphorus 4.8 mg, cholesterol 170 mg, urea 13 mg, sugar 93 mg. The Wassermann reaction of the blood (Kolmer and Kahn modifications) was negative. The basal metabolic rate was plus 9 per cent.

Pachon oscillometric readings revealed normal conditions in both calves and ankles. X-ray examination of the sella turcica showed the pituitary fossa to be slightly larger than average. The lateral film of the skull showed no evidence of increased intracranial pressure.

During her stay at the hospital, the patient complained of severe pains in the shoulders, legs and abdomen. On one occasion, the pains were so severe that a hypodermic administration of morphine had to be resorted to. The question of focal infection with arthritic changes was considered. Clinical and X-ray studies of all the teeth and the joints of the upper and lower extremities were negative. The shafts of the left femur and fibula were normal in appearance. Dr J R Moore excluded any orthopedic condition that would be responsible for her pains. The pains were therefore attributed to her metabolic disorder. She was discharged with the diagnosis of Dermum's syndrome and was referred to the Endocrine Clinic. On her visits to the clinic she still complained of pains and marked weakness. Because of her extreme exhaustion and our experience with prostigmine and aminoacetic acid in case 1, she was tested by Dr Farrar for myasthenic reaction of the muscle. He found a marked improvement in contractions of the left sternocleidomastoid muscle (faradic current stimulation) after intramuscular injection of 1 cc of 1:2,000 solution of prostigmine. The patient was placed on a diet consisting of 70 Gm of protein, 100 Gm of carbohydrate and 70 Gm of fat. She was given 15 mg of prostigmine orally three times a day. For the pains and nervousness, analgesics in the form of acetylsalicylic acid and phenobarbital were given with satisfactory results. The weakness, however, persisted although not so pronounced. Aminoacetic acid 7 Gm daily was added. The weakness disappeared in the course of twenty-four days. The vasomotor phenomena were combated by sedatives and intramuscular injections of estradiol benzoate. After four months of treatment, the patient lost 40 pounds (18 Kg) and was able to carry on her usual household duties. Prior to administration of aminoacetic acid the urine contained 0.23 Gm of creatine for twenty-four hours. Five months later it showed a creatine content of 0.27 Gm. After omission of aminoacetic acid for a period of one month, the twenty-four hour urine creatine rose to 0.330 Gm. After this treatment had been resumed for three weeks, the twenty-four hour urine creatine decreased to 0.242 Gm. It is interesting to note that during her treatment and while she was losing weight, three attacks of epigastric discomfort developed with pains in the right

1a. Muscle fatigued at ninety contractions—twenty-five mg of prostigmine intramuscularly showed no fatigue after 150 contractions upward.

upper quadrant simulating gallbladder disease. A cholecystogram showed no evidence of an opaque or nonopaque calculus in the gallbladder and a normally functioning gallbladder. Biliary drainage, however, showed many cholesterol crystals in the bile sediment. The upper abdominal pains cleared after several biliary drainages.

CASE 3—Mrs. A. T., aged 48, admitted to Temple University Hospital June 17, 1937, complained mainly of weakness of the back and the legs, pain in the right hip and increasing weight. Her previous health had been good until three years before, when she noticed that her strength was decreasing and that she had no "support" in her back. She had great difficulty in sitting up from a recumbent position and had to hold on to something to pull herself up. The pain in the right hip region particularly when lying on this side, she had had for three years. She had typhoid at the age of 15 years and a nervous breakdown nine years before admission. She was married and had had four pregnancies. The first infant died shortly after birth. Her three boys were vigorous at this time.

Her menstruation was regular and of normal flow. She weighed 175 pounds (79.4 Kg.) and was 5 feet (152 cm.) in height. The fat was universally distributed with lipomatous masses about the hips and subtrochanteric areas. These fatty masses were very tender on pressure. There were many tender nodules smaller in size scattered over the thighs and arms suggesting bag of worms feel as described by Dercum. There was weakness of the back and leg muscles particularly of the psoas iliacus group. No fibrillary twitchings of the muscles were noted. There was a marked lumbar lordosis. On her attempt to rise from the floor the patient rotated her whole body getting on all fours. The neurologic examination by Dr. S. F. Gilpin, Jr. revealed no central or spinal cord involvement. The visual fields and retinas were normal. Examination of the chest showed no evidence of heart disease. The lungs were clear. The blood pressure in millimeters of mercury was 110 systolic and 80 diastolic. The abdomen was negative except for the presence of an apron of fatty tissue containing isolated tender lipomatous nodules. The pelvis was normal. The Wassermann and Kahn reactions of both the blood and the spinal fluid were negative. The colloidal gold curve of spinal fluid was negative. The basal metabolic rate was plus 6 per cent, the blood cholesterol was 165 mg. per hundred cubic centimeters of blood, blood calcium was 12 mg. and blood phosphorus 4.4 mg. The fasting value of the blood sugar was below normal (78 mg.). The sugar tolerance test showed an increased tolerance for carbohydrates. The blood count was: hemoglobin 13 Gm. per hundred cubic centimeters of blood, red blood cells 5,060,000, white blood cells 10,500, polymorphonuclear leukocytes 54 per cent, lymphocytes 33 per cent, monocytes 12 per cent and eosinophils 1 per cent. The red blood cells were normal. Urinalysis reaction pH 7.0, specific gravity 1.010, albumin slight trace, sugar negative, occult blood was slightly positive. An occasional red blood cell was present and an occasional white blood cell with many bacteria. X-ray examination of the skull showed a normal sella. X-ray examination of the chest revealed no pathologic changes. The faradic stimulation of the left extensor indicis proprius muscle showed no myasthenic reaction. A twenty-four hour specimen of urine contained 0.869 Gm. of creatinine and 0.071 Gm. of creatine.

The patient was placed on a diet of 1,500 calories with aminoacetic acid 10 Gm. and prostigmine 45 mg. daily. After ten days treatment the patient's fatigability decreased and she had a feeling of general well being. After two months her general strength increased to such an extent that she was able to attend to light household duties. However the lumbar muscle group was not beneficially affected. At the present time she is taking 15 Gm. of aminoacetic acid daily which is apparently her maintenance dose.

This represents a case in which the symptoms of adiposis dolorosa were complicated by symptoms suggesting muscular dystrophy. Aminoacetic acid appeared to be of benefit for the relief of the asthenia.

COMMENT

The diagnosis of adiposis dolorosa in many instances is a difficult one. It is based on the presence of painful nodular obesity associated with asthenia and psychoneurotic manifestations. In cases 1 and 2 the clinical picture was fairly definite. In case 3, in addition to the adiposis dolorosa syndrome, the element of progressive muscular dystrophy is strongly to be entertained. That the nodules are not those of von Recklinghausen's disease is indicated by the fact that, in the latter, they are smaller and firmer and they follow along the course of nerve trunks. A biopsy of fatty nodules in cases 2 and 3 showed them to consist of fatty tissue. Myxedema is not to be considered, since in cases 2 and 3 the basal metabolic readings were above normal and the blood cholesterol estimation gave low figures. In case 1 the basal metabolic rate was minus 25 per cent, however the blood cholesterol was 138 mg. per hundred

Fig. 3 (case 3).—Patient presenting nodular type of Dercum's disease.

cubic centimeters, then again she presented painful fatty nodules and she failed to improve when placed on sufficiently large doses of desiccated thyroid, which raised the basal metabolic rate to practically a normal level. Adiposis dolorosa has frequently been associated with a hypopituitary state, as in case 1. The low basal metabolic rate is to be looked on as conditioned by the latter endocrinopathy.

The peculiar reaction of the sternocleidomastoid and the extensor indicis proprius muscles to the faradic current stimulation raises an interesting question of the coexistence of an abnormal muscle metabolism not unlike that seen in myasthenia gravis. This view finds support in the fact that after intramuscular use of prostigmine muscle contractions could be elicited for a longer period before weakening than prior to the administration of prostigmine. The response of the muscles to the injection of prostigmine has been striking. This immediate improvement following a single injection of prostigmine is characteristic of myasthenia

² Dercum, F. N., cited by Wohl, M. G., and Pastor, Nathan. *Adiposis Dolorosa*. *Cyclopedia of Medicine*. Philadelphia: F. A. Davis & Co., 1938.

gravis, according to Harvey and Whitehill.³ It was shown by Folin⁴ and later by Klercker⁵ that the normal adult excretes no creatine or only a very small amount, especially in the case of the female. In certain myopathies, however, creatine in the urine is materially increased.⁶ Tripoli⁷ and Remen⁸ observed creatinuria in myasthenia gravis. Edgeworth⁹ states that a creatinuria and a lowered excretion of creatinine are found in this disease. In this connection the high creatine values in our cases are significant. Aminoacetic acid is known to play an important role in creatine metabolism. According to Boothby¹⁰ it is of definite benefit in myasthenia gravis. The marked

asthenia in cases 1 and 2 was considered to bear some relationship to a disturbance of muscle metabolism analogous to that seen in myasthenia gravis. This new view suggested the use of prostigmine and aminoacetic acid. Prostigmine alone had less beneficial effect in overcoming the asthenia than when it was combined with aminoacetic acid. During the studies on adiposis dolorosa we observed that aminoacetic acid was of decided benefit in four patients with obesity in whom a reduction in caloric intake produced extreme weakness. The inclusion of aminoacetic acid in their food enabled the patients to continue with a subcaloric diet and to lose weight satisfactorily. Investigation of this problem is in progress.¹¹

SUMMARY

In three patients presenting the syndrome of adiposis dolorosa, asthenia was a prominent feature. Two cases presented signs of myasthenia gravis (myasthenic reaction and creatinuria). In these two cases the administration of aminoacetic acid and prostigmine resulted in marked improvement. The third case showed symptoms suggestive of associated muscular dystrophy. Aminoacetic acid improved her general condition, however, the muscles of the back (muscular dystrophy) responded less favorably.

DRAINAGE OF CEREBROSPINAL FLUID

IN TREATMENT OF HYDROCEPHALUS, SYRINGOMYELIA AND SYRINGOBULBIA

N D ROYLE, MD, CHM, FRACS
SIDNEY, AUSTRALIA

The physiologic result of cutting the sympathetic nerves is to dilate the arterioles and venules. It necessarily increases the rate of capillary flow and thereby relieves edema.

It has been shown by Forbes and Wolff¹ that the cerebral blood vessels are under the control of the sympathetic nervous system, and I have shown that the brain on the side on which the stellate ganglion has been removed is pink in contrast to the bluish color of the contralateral side, that the anastomosing vessels appear less numerous and that the brain gradually shrinks away from the parietes on the ipsilateral side. These phenomena are displayed when the brain has been exposed.

The shrinkage of the brain on the ipsilateral side suggested to me that the operation of superior thoracic ganglionectomy might be used in the treatment of hydrocephalus. I treated two patients in this manner. The following is a short account of each case.

CASE 1—A boy, aged 14 years, had a normal birth. Three weeks after birth he had convulsions and was subject to fits for ten years. There had been no fits for four years prior

Fig 1 (case 2)—Patient two years before operation showing normal head

to his coming under observation. The fits used to last from four to five hours. Enlargement of the head was first noticed one month after the first convulsion and it continued to enlarge until the time of operation when it measured 61 cm in circumference. The patient had never walked, he had contractures of the hamstrings and plantar flexing muscles of each lower limb. On account of paresis of the quadriceps the knee jerks were unobtainable but there was an ankle jerk increased in excitability and slower than normal in relaxation. The patient was mentally defective though not to a severe degree. He had never been educated.

The operation of superior thoracic ganglionectomy was performed on each side in May 1931. Since the operative treatment his head has ceased to enlarge and on June 29 1932 measured 61 cm in minimum circumference. There has been some improvement in intelligence. After this date I lost sight of the patient.

CASE 2—A youth, 18 had a normal birth. His head was so enlarged at 3 months of age that his bonnets had to be made to measure. When first seen in June 1926 he had

spastic paraplegia, for which condition I performed a lumbar sympathetic ramisection on each side. This enabled the patient to gain his balance and improve his walking. He was able to run after the operation, whereas he was not able to do this prior to the operation. When examined in April 1932, the knee jerks still exhibited phasic response of considerable range and were retarded in relaxation and the oscillations were absent. The right side showed these phenomena more defi-

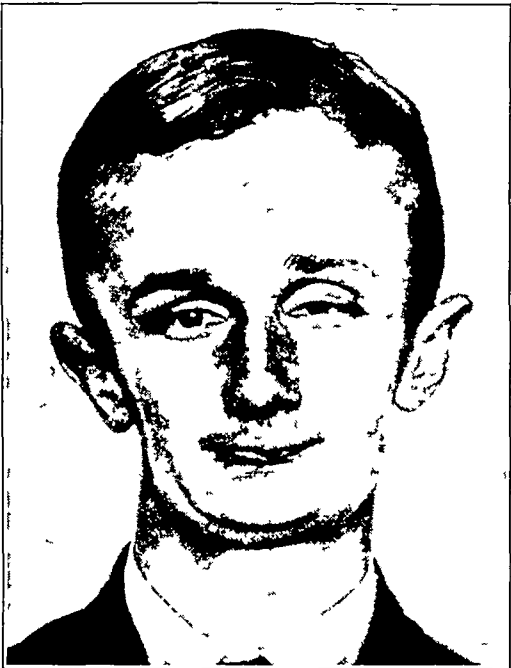

Fig 2 (case 2)—Flattening of head on left side eighteen months after operation. Note paler color of left ear.

nitely than the left. The Babinski reaction was positive on both sides. The patient walked well but dragged his right foot. His head measured 67.7 cm in circumference and according to his parents was increasing in size. He was slightly mentally defective and had the intelligence of a boy of 14. His memory was defective; he could not remember recent events. The patient had had constipation before the first operation but this had been relieved. Before the present operation he had frequency of micturition during excitement as when watching a football match and also in cold weather.

Changes in Measurement of Head

| | Anteroposterior Diameter Cm | Lateral Diameter Cm | Circumference Cm |
|----------------|--------------------------------|------------------------|---------------------|
| May 2, 1932 | 22.75 | 18.75 | 67.6 |
| June 13 | 22.4 | 18.6 | 66.8 |
| October 22 | 22.5 | 18.3 | 66.8 |
| March 29, 1933 | 22.5 | 18.5 | 66.7 |
| July 15, 1934 | 22.6 | 18.6 | 67 |
| Sept 9, 1936 | 22.4 | 18.8 | 67.3 |

The operation of the left superior thoracic ganglionectomy was performed on the patient April 30, 1932. The frequency of micturition became normal. His head began to shrink immediately, so that in six months it measured 67 cm. Measurements taken with calipers and steel tape showed the changes in size given in the accompanying table.

This is, I believe, the first instance in which an operation for hydrocephalus has been followed by definite decrease in size of the head. This result is probably due to the relief of edema of the soft tissues of the scalp (figs 2 and 3).

The application of sympathetic surgery to syringomyelia was not intentional.

CASE 3—A girl aged 17 years suffered from aching feet, clawed hands and vasomotor changes in both upper and lower

limbs, which were usually purple. In winter she suffered from chilblains. The pupils were small but not pinpoint. Her knee jerks were exaggerated in phasic response and there was a prolonged postural response. She had a wrist jerk of similar type. She had loss of balance in both lower limbs and had a spastic gait. There were sensory changes in both upper and lower limbs, particularly with regard to perception of heat and cold. Her condition was diagnosed by Dr A. W. Holmes, a Court, honorary physician at Sydney Hospital, as syringomyelia. Lumbar sympathetic ramisection on the right side was performed April 29, 1930, on account of loss of balance and spasticity in the lower limbs and gave surprising results. Not only did the spastic gait cease to affect the patient in both lower limbs but the clawing of the hands gradually diminished and the purple color of the limbs disappeared also. When examined two years later her condition was normal excepting that perception of heat and cold was still inaccurate but improved.

I did not appreciate this result until I saw a patient suffering from syringobulbia. I then realized that drainage of the cerebrospinal fluid had been effected.

CASE 4—Three years ago the patient was thrown from a horse and fell on the right side of his neck. Headache developed six weeks later and continued up to the time of operation. The pain was referred to the front of the right ear and radiated down the shoulder in the region supplied by the cervical plexus. The right hand and arm had been numb and clumsy for three years. The right arm also felt heavy, and he had noticed twitching in it for some time. He had also noticed that the fingers of the right hand appeared shorter than those of the left hand. On looking to the right he had double vision.

On examination the patient had ptosis of the right eyelid and nystagmus of both eyes to the left. The pupils were small but reacted to light and in accommodation. He had paralysis of the right half of the soft palate. He had loss of power in the right arm and shoulder. He had loss of sensation in the right half of the face and loss of heat and cold sensibility and pain in the area supplied by the

Fig 3 (case 2)—Back view showing flattening of head on left side. Note paler color of left ear.

cervical plexus. The knee jerk gave an active phasic response with absence of oscillations on the right side and normal oscillations on the left side. The patient fell to the left when walking and could not balance on his right lower limb. His tongue was paralyzed on the right side (fig 4A) and there were fine fibrillary twitchings on this side. When protruded it turned to the right.

Dr J. D. Herlihy, honorary physician at Lewisham Hospital, diagnosed his condition as syringobulbia.

The operation of superior thoracic ganglionectomy was carried out March 20, 1936, with the following results

Within a few days the pain on the right side of the face became very much less. Nystagmus gradually disappeared and is now almost gone. The tongue was gradually restored

Fig 4 (case 4) —A paralysis of right half of tongue before operation B recovery of right half of tongue six months after operation

to normal condition. It can now be protruded normally (fig 4B), and the fibrillary twitchings are less evident. The soft palate has recovered. He has lost the staggering gait and stands well on either lower limb. He can now see farther to the right than he could before the operation.

COMMENTS ON THESE CASES

The operation of superior thoracic ganglionectomy causes an increase in the rate of capillary flow in the

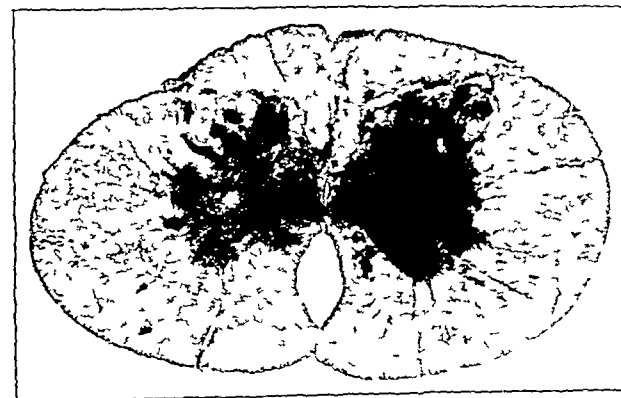

Fig 5—Greater drainage on the ipsilateral side after a left lumbar sympathectomy. The animal was electrocuted after being lightly anesthetized. Specimen obtained six weeks after operation.

cervical region of the spinal cord and of the brain. The operation of lumbar sympathectomy increases the rate of drainage on the ipsilateral side of the cord in the lumbar region as shown in figure 5. Both operations provide an outlet for the cerebrospinal fluid where they tap the spinal circulation. It is just as if a drain were placed in either position. In contrast to the other methods of draining the cord, this method has the virtue of permanence.

There has been a boggy raised recently in the shape of the effect of epinephrine on sympathetically denervated structures. It is said that the denervated structures are more sensitive to epinephrine. If this is so, why does Horner's syndrome persist in patients who underwent operation eight or ten years ago, or who have the effects described in this paper persisted in one case for seven years and in another for five years.

In my opinion, epinephrine has no more effect or not as much effect on denervated sympathetic structures as it has on normal structures, and this is shown by operative results in hundreds of patients.

In my experiments on the effect of epinephrine and ephedrine on muscle tone, the sympathectomized limb was the only one that did not show an increased tone under the influence of large doses of epinephrine. This shows that epinephrine did not affect the spinal blood vessels.

CONCLUSIONS

1 Superior thoracic ganglionectomy is effective in causing increased drainage of cerebrospinal fluid in chronic hydrocephalus and syringobulbia.

2 Lumbar sympathectomy is an effective treatment for syringomyelia.

3 Epinephrine has little effect after sympathetic denervation.

Clinical Notes, Suggestions and New Instruments

UNUSUAL FRACTURE DISLOCATIONS OF CERVICAL SPINE

HERMAN B. PHILIPS, M.D., NEW YORK

This case history shows how severe an injury to the upper part of the cervical spine may be without any permanent disability. Several very unusual features in this case make it worthy of presentation.

During May 1936, while working as a stevedore, the patient was struck on the back of the neck by a falling log weighing 700 pounds and knocked from the dock on which he was working to an adjacent lighter. He lost consciousness for several hours and was taken to a hospital, where he remained in bed for about a month and then was permitted up and about until he was discharged from the hospital about a week later. He sustained lacerations of the scalp and an injury to the upper part of the neck and stated that X-ray examination showed a fracture of one of the vertebrae. According to his story, there was no vomiting or double vision at any time. One lumbar puncture was performed, but the results were unknown to him. For a day or two after the injury the patient cleared blood from his nose but did not bleed from his ears. He complained of deafness in the right ear about a month after the injury. About the middle of June and early in July he experienced a sudden transient complete loss of vision in the right eye. The pain in the back of his neck and head showed gradual improvement. The pain was increased by turning the head to the left and also increased by lying on one side for a prolonged period. The rest of the history is irrelevant as far as this injury is concerned.

EXAMINATION

The physical examination, except for the neurologic examination, was irrelevant. The neurologic examination, by a competent neurologist, showed the following:

Cranial Nerves—1 The sense of smell was normal.
2 The fundi and visual fields were normal. Acuity was tested.

3 Royle, N. D. The Increase in Muscle Tone Following Section of the Sympathetic Nervous System. *M. J. Australia* 1, 40 (June) 1929.

3, 4 and 6 Both pupils were slightly irregular but reacted normally The eye movements were normal

5 Corneal and nostril reflexes were equal and active The motor component was normal The patient claimed decreased sensibility in the right cheek and temple, but the responses to touch and pain stimuli were inconsistent and the normal corneal and nostril reflexes were incompatible with an organic sensory loss

7 There was no facial weakness

8 Sound was lateralized to the right and there was impaired bone and ear conduction in the right ear Semicircular canal function could not be tested by rapid head movement because of the stiffness of the neck muscles

9 to 12 The palate and tongue movements were normal

Other Tests—Examination of the motor system showed no swaying on the Romberg test There was no tremor weakness or ataxia The sensory system was normal The tendon and superficial reflexes were normal and equal on the two sides The mental status was normal

The Head—There are recently healed scars of scalp lacerations One about 2½ inches long is in the right upper mid-parietal region and is nonadherent and nontender The other scar about 2 inches long, is to the left of the midline just about the bregma and there is a slight depression along the line of the scar which is cleanly healed and nontender There is no other skull abnormality The patient holds his head rather stiff most of the time, and the right lateral and posterior cervical muscles are tense and tender to pressure

Opinion based on the history and physical manifestations is that there are (1) lacerations of the scalp, injury to the neck, and a moderately severe cerebral concussion (2) no signs of intracranial or spinal cord injury at the present time and no postconcussional symptoms, and (3) pain in the area supplied by the second and third cervical nerves on both sides due to injury affecting the muscles and ligaments of the neck and would be a normal consequence of any accompanying fracture

ROENTGEN EXAMINATION

There are multiple fractures of the atlas and axis with dislocations of the articulations between the atlas and the skull and the atlas and the axis

The posterior arch of the atlas has sustained two complete transverse fractures which are not united They are clearly seen in the lateral and vertex occipital roentgenograms (figs 2 B and 1 4) On the right side the fragments are separated by about one fourth inch and on the left side by about one-eighth

Fig 1—A vertex occipital view showing posterior portions of neural arches of upper cervical segments projected through the foramen magnum Asymmetry and deformity are apparent B submento occipital view showing anterior portions of neural arches of upper cervical segments with fractures and deformities Roentgenogram retouched

inch The fracture on the right side is comminuted with a small intermediate fragment The extreme posterior portion of the posterior arch, which is about 2 inches in length is displaced posteriorly and to the left side There are no evidences whatever of any attempt at bony union this posterior portion of the arch being unattached by bone structures to any of the adjoining portions of the spine

There are multiple fractures of the anterior arch of the atlas At least two complete fractures are present one on the right

side and one on the left side of the tubercle These fractures are united with considerable deformity and irregularities in contour of the bone Spur formations are produced on the anterior margins of the arch and the tubercle is displaced to the left of the midline by one-fourth inch and to the left of the midplane of the odontoid process by one-half inch (fig 1 B) All of them should be in the same plane The entire atlas is spread out peripherally, the anterior arch being displaced anteriorly, the lateral portions of the atlas which include articular and transverse processes are displaced laterally, and the posterior arch is displaced dorsally and to the left

The space between the anterior surface of the body of the axis and the posterior surface of the anterior arch of the atlas is twice the normal width (fig 1 B) This is due to the spread

Fig 2—A anteroposterior view of upper cervical spine through open mouth Shows asymmetry of atlanto-axial articulations B lateral view of upper cervical segments showing fractures of posterior portions of neural arch of atlas and of styloid process of temporal bone

of the anterior portion of the arch of the atlas as well as to anterior displacement of the atlas with respect to the axis This anterior displacement is asymmetrical, owing to rotation anteriorly to the left side of the atlas

There is a longitudinal fracture of the anterolateral portion of the body of the axis adjoining the base of the odontoid process on the right side The fracture is seen in all of the mento occipital exposures (fig 1 B) The fracture appears united, but there is an associated irregularity in contour of the base of the odontoid process, as a result of the fracture There is also some irregular density extending completely across the body apparently along the united fracture line As a result of this fracture the odontoid process is angulated slightly to the right side at an angle of approximately 10 degrees

The separation of the fragments of the atlas has resulted in partial dislocations of the articulations between the skull the axis and the atlas Both the lower articular surfaces of the atlas are displaced outward one-fourth inch with respect to the corresponding articulations of the axis and the skull (fig 2 A) The anterior rotational displacement of the left lateral portion of the atlas contributes to an additional dislocation so that the articular surface on the left side between the atlas and the axis is almost completely obliterated in the anteroposterior roentgenogram The occipital condyle (the articular process of the base of the skull) is clearly defined on the right side, as is also the articulation between it and the articular process of the atlas but on the left side there is a definite overlapping of shadows showing a subluxation of this articulation Apparently in addition to there being a bilateral outward displacement of the articular process of the atlas there is also an anterior displacement on the left side which produces an additional subluxation with respect to the atlas below and the occipital condyle skull) above (fig 2 A)

There is, in addition an incompletely united fracture of the styloid process of the left temporal bone (fig 2 B)

COMMENT

The injuries sustained in this case are usually associated with compression or lacerations of the spinal cord or hemorrhage into or near the brain stem or base of the brain and are usually fatal but in this instance in spite of an unusually severe combination of fractures and subluxations there was a coincidental decompression by peripheral displacement of fragments and their subsequent nonunion which contributed in no small degree to the patient's recovery

The peripheral displacement of the fragments of the atlas and their nonunion subsequently were as effective as an actual

decompression operation, and this undoubtedly saved the patient's life. The case illustrates, notwithstanding prevalent notions to the contrary, that extensive severe injuries in close proximity to vital structures are compatible with fairly complete recovery and reasonably good health. The case also indicates the necessity for thorough roentgenographic study. More than forty roentgenograms were made during several examinations over several weeks, until completely satisfactory exposures were secured. When first seen soon after a severe injury, thorough examinations should not be undertaken, for positioning the patient for demonstrating fractures and dislocations of the uppermost segments of the spine, such as in this case would undoubtedly jeopardize the life of the patient. As the patient recovers and a safe period is reached, more thorough roentgenographic studies can be made with impunity.

9 West Sixty-Eighth Street

POSTMORTEM VERIFICATION OF ANTERIOR POLIO MYELITIS IN A MAN OF ADVANCED YEARS

MAX J. FOX, M.D., MILWAUKEE

Assistant Superintendent, City of Milwaukee Isolation Hospital

During the months of July, August, September and October 1937 the city of Milwaukee had a mild epidemic of poliomyelitis. During this time 110 patients were interned at the city isolation hospital for medical services.

Among these patients was one in particular whose case seemed worthy of adding to the medical literature because of the advanced age of the patient.

Correspondence with superintendents of contagious disease hospitals in the United States failed to bring to light any patient with poliomyelitis approaching the age of this one. Dr. Josephine B. Neal states that in 1914 she had a patient aged 55, in 1916 a patient aged 58 and in 1921 a patient aged 50. Lavinder, Freeman and Frost¹ found seven patients between the ages of 45 and 64 in the epidemic of 1916 in New York City. Forsbeck and Luther² reported on the mass epidemic of 1908 to 1929 in which there were four instances between the ages of 55 and 59. My patient seems to be the oldest on record to date as having died of poliomyelitis.

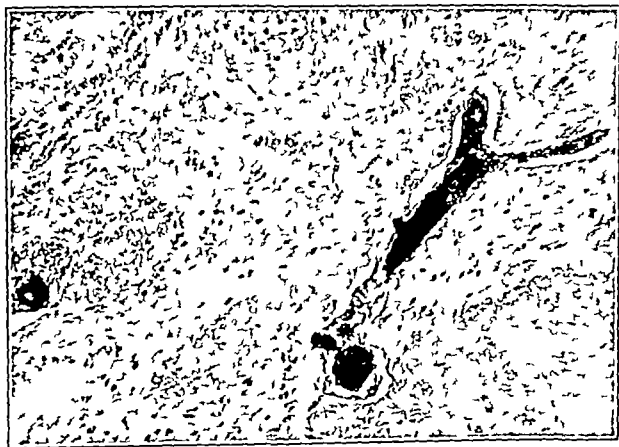

Fig. 1—Section from the dilated blood vessels of the pons filled with stagnant blood. Around the vessels there is a collar of lymphocytic infiltration. Somewhat distant from the vessels there is some perivascular edema.

REPORT OF CASE

E. H., a man, aged 68, a painter, entered the hospital with almost total paralysis of both legs. Four days prior to this an infection of the upper respiratory tract, a cough and general malaise had developed. Two days later he began having pain

in the lower part of the back and the thighs. This was followed by a gradually increasing weakness in the lower extremities and by evening he was unable to walk. The next morning he was able to move only his toes. The following day he was brought to the hospital.

The patient's family and past personal history were normal except for an injury to the lower part of the back sixteen

Fig. 2—Microscopic study under low power of section from cervicod showing a blood vessel which is filled with erythrocytes. There is also perivascular lymphocytic infiltration. The tissue outside the vessel appears edematous and contains lymphocytes scattered throughout.

thirty-three years before and a back strain received while he was lifting a heavy object about one week before his entrance to the hospital.

On physical examination at the time of entrance to the hospital the patient, a slender man, was partially paralyzed but apparently not acutely ill. Physical and neurologic examinations of the head were negative except for a coryza and a mild pharyngitis. There was no rigidity of the neck or adenopathy. Examination of the chest was negative except for a few scattered fine rales in the bases of both lungs. The heart was normal with a blood pressure of 130 systolic and 80 diastolic. Examination of the upper extremities revealed a slight tremor and a slight amount of muscular incoordination. The reflexes of both biceps and triceps were slightly exaggerated. No muscular weakness was evident. The Kernig and Brudzinski signs were both absent. Both lower extremities were flaccid except for weak flexion and extension of the toes, weak dorsiflexion of the left foot and weak adduction of the right thigh. There was a slight amount of tenderness over the calf muscles on pressure, but no other sensory disturbance was present. The patellar and achilles reflexes were absent. There was no ankle clonus, and Babinski's sign was absent. There was an absence of the abdominal and cremaster reflexes.

A lumbar puncture was done and 5 cc. of clear fluid was drawn under normal pressure. The Queckenstedt test was positive. The spinal fluid cell count was 205 cells per cubic millimeter, predominantly lymphocytes. Urinalysis was negative. The blood count was essentially normal except for a moderate leukocytosis of 8250 white blood cells per cubic millimeter with a differential count of 64 per cent polymorphonuclears, 25 per cent lymphocytes and 11 per cent monocytes.

A diagnosis of poliomyelitis was made.

On the following morning another lumbar puncture was done and three-eighths gram (0.024 Gm.) of ephedrine sulfate and 2 cc. of physiologic solution of sodium chloride was injected intrathecally. Examination of the spinal fluid showed an increase in globulin, chlorides were 718 mg. per hundred centimeters, the Ross-Jones and Noguchi tests were negative as were the Wassermann and Kahn tests. The colloidal curve was 0000000000. A cell count of the spinal fluid at this time was 106 cells per cubic millimeter (100 per cent lymphocytes).

¹ Lavinder, C. H., Freeman, A. W. and Frost, W. H. Poliomyelitis. Report of the International Committee. Baltimore: Williams & Wilkins, 1932, p. 388.

² Forsbeck and Luther. Poliomyelitis. Report of the International Committee. Baltimore: Williams & Wilkins, 1916, p. 411.

During the next twenty-four hours, except for considerable coughing and the presence of large moist rales over the bronchi, the patient's condition was unchanged. There was no increase in the amount of paralysis. A beginning pneumonia was suspected at this time.

On the following morning the patient became quite cyanotic, respirations were rapid and labored, and the pulse was rapid but of good quality. The temperature rose to 103.2 F. There was percussion dullness over both lung bases. Diminution of breath sounds and many moist rales were present confirming the diagnosis of pneumonia. Respiratory stimulants and nasal oxygen were given, to which the patient responded weakly. The next morning, ten days after the onset of his illness, the patient failed suddenly and was found dead. An autopsy was performed by Drs. J. C. Grill and L. J. Van Hecke of the pathologic department of Marquette University.

SUMMARY OF MACROSCOPIC AND MICROSCOPIC EXAMINATIONS

The body was of a well developed and well nourished man.

The pupils were unequal, the left measuring 3.5 mm and the right 5 mm in diameter.

There was moderate abdominal distention.

The lungs were voluminous. The pleural cavities were normal. In both the right and the left lung were scattered foci of aspiration, apparently bronchopneumonia with small areas of necrosis in the lower portion of the left upper lobe. The bronchi contained a thick, purulent material. The mucous membranes were thickened and injected.

The heart showed no macroscopic changes. The arch and descending aorta presented a moderate atheromatosis.

The liver had a moderate cloudy swelling with a loss of normal markings.

The spleen was slightly enlarged with a soft grayish red parenchyma.

The kidneys were moderately swollen. The urinary bladder was considerably distended with a clear yellow urine. The prostate was enlarged and had small adenomas in the lateral lobes.

Aside from distention, the gastro intestinal tract was without marked change.

Fig 3—Low power section from the lumbar cord. In the periphery of the section one notices an infiltration of the leptomeninges with lymphocytes and a few polymorphonuclear leukocytes. The remaining section presents a similar microscopic picture as in figure 2, viz. stagnant blood in the vessels, perivascular infiltration, lymphocytic infiltration of the remaining tissue with some proliferation of microglia.

There was hypertrophic lipping of the edges of the vertebral bodies of the spine which was most marked in the lumbar region.

The skull showed no pathologic change. The leptomeninges of the brain were congested. The cortex of the brain was of a violet color giving a sharp contrast to the white matter. Otherwise there were no obvious macroscopic changes. The spinal cord revealed congestion of the leptomeninges but nothing further was obvious.

On microscopic examination all sections revealed an increased number of leukocytes within the blood vessels.

Microscopically the heart was normal.

The lungs had a purulent bronchitis and bronchopneumonia with marked necrosis in some portions.

The liver had a finely granular liver cell cytoplasm. There were no nuclear changes and while the sinusoids contained

Fig 4—Section of lumbar cord under high power. There is marked degeneration of the ganglion cells. The surrounding tissue presents a lymphocytic infiltration and proliferation of microglia. The blood vessels are filled with stagnant blood and present perivascular infiltration and edema.

numerous leukocytes there was only a moderate swelling of the tubular epithelium and a very occasional lymphocytic infiltrated scar. The glomeruli were normal.

The prostate evidenced a fibromuscular hypertrophy.

The spleen suggested the appearance of a reticulum hyperplasia and some of the monocytes had phagocytized red blood cells. The malpighian bodies were moderately hyperplastic.

The adrenal gland and pituitary gland showed no obvious changes.

Microscopic sections of the central nervous system demonstrated many changes. All sections of the cord revealed degeneration of the anterior horn. In some of these degenerated areas were extravascular red blood cells, especially in the most degenerated portions. This degeneration was either on both sides or on one side. The degeneration was evidenced by various alterations of the nerve cells which ranged from simple swelling with slight eccentricity of the nucleus to complete loss of pigment nucleus and nucleolus. The principle cell of evolute appeared to be a mononuclear cell with a nucleus of horseshoe shape, the cytoplasm of which for the most part was foamy. There was a scattering of polymorphonuclear leukocytes and a few small round cells. The small round cells, however, were in superabundance in the perivascular spaces not only in the anterior regions but in all other portions of the cord as well and even in some parts of the leptomeninges. In one section of the thoracic cord degeneration seemed to have extended out into the lateral fasciculus, and elsewhere it remained practically confined to the region of the anterior horn. There were no obvious changes in the cells of the column of Clarke. On section of the posterior sensory ganglion an apparently normal structure was found; however, one or two cells in each section had undergone obvious degenerative changes. In these sections, however, there was no perivascular round cell infiltration.

In sections higher up on the cord there was a continuation of the same process, and in the medulla at the olivary nucleus there was definite perivascular round cell infiltration but relatively little obvious degenerative change. Sections from the lower pons had a similar appearance with very early nerve cell infiltration but no obvious nerve cell degeneration. The ventricular ependyma and the basal nuclei showed no obvious alterations. There were no alterations either of structure or of the blood vessels in the cerebral cortex and cerebellum. The leptomeninges in the sections of cord had somewhat

increased numbers of small round cells in the arachnoid spaces and a slight perivascular round cell infiltration. There were lymphocytes in the leptomeninges of the brain but no typical collars around the blood vessels.

The microscopic diagnosis was (1) acute anterior poliomyelitis (2) purulent bronchitis (3) aspiration pneumonia with beginning gangrene of the lung, (4) parenchymatous degeneration of the liver and kidney (5) mononuclear erythrophagocytosis of the spleen and (6) lymphocytic infiltration of the leptomeninges.

COMMENT

In this case the clinical picture, the laboratory studies and the postmortem examination conform to the pathologic changes expected in anterior poliomyelitis. There was nothing revealed to evidence any other clinical entity.

CONCLUSION

This disease should be known as anterior poliomyelitis.

It occurs with greatest frequency in the young, occasionally in older persons. The present patient appears to be the oldest person on record as having died of this disease.

BACILLUS VIOLACEUS INFECTION IN A HUMAN BEING

M. E. BLACK, M.D. AND JOHN SHAHAN, M.D. CLEARWATER, FLA.

Bacillus violaceus is ordinarily considered nonpathogenic. Woolley¹ however, described several fatal cases in animals due to a strain of this chromogen, but so far as we have been able to ascertain no cases of infection of human beings with this organism have been described. We therefore present the following case.

REPORT OF CASE

History.—S. P., a white boy, aged 6 years, admitted to the Morton T. Plant Hospital on the afternoon of Aug. 17, 1937, had been ill for three days. He had been a normal child in all physical respects and had had but one illness before this time. Some months previously he had suffered from an acute inguinal adenitis which caused elevation of temperature and

Fig. 1—Appearance of left arm Aug. 30, 1937.

chills for a few days and then subsided. This was thought to be due to an infection of the lower extremity of the affected side.

Two or three days prior to the onset of the present illness he, with a number of children, had been wading in a pool of rain water which had collected in a low spot of ground. At the onset of illness he had an elevation of temperature and complained of pain in the right inguinal region. There was some tendency to nausea and vomiting, but there were no other subjective symptoms of note.

Examination.—The patient was well nourished and appeared to be seriously ill, he was irrational. A profuse perspiration was present, despite a temperature of 101 F. Inspection revealed from eight to ten skin lesions appearing on the flexor surface of the left arm just above the elbow, on the lateral surface of the right elbow and on the right side of the trunk; the latter ones were distributed over the ventral and dorsal surfaces. There were also several of the lesions low down on the right anterior abdominal wall. The glands in the right inguinal region were quite swollen and tender. The left arm exhibited a marked cellulitis and lymphangitis with tender and swollen glands in the left axilla. It appeared that these were

Fig. 2—Appearance of right arm Aug. 30, 1937.

suppurate in a short time. The appearance of the cutaneous lesions was distinctive and at first looked like those of anthrax. However, a difference was to be noted. These varied in size from one-half by 1 inch to one or two that were twice that size. In each there was a dark mahogany red eschar, slightly depressed and dry. Each of these was surrounded by a pustular area, which showed a distinct violet color in the surface of the pustular ring. The pus was semithick and yellowish white. It was nonodorous and not very profuse.

Except for these cutaneous lesions, the physical examination gave negative results.

Smears from the lesions showed a slender gram-negative bacillus about the size of *B. typhosus*, arranged singly in pairs and in groups, and repeated agar cultures of material taken from each of the lesions produced discrete deep violet colonies, the color remaining on or very near the surface and not diffused throughout the medium. The pigment was slightly soluble in water and quite soluble in alcohol. The growth emulsified with difficulty. Microscopically, from cultures, the organism showed vacuoles resembling spores, but these clear areas did not take the spore stains. The organism was killed completely at boiling temperatures. No gas was produced in the ordinary sugar mediums, and only in glucose was there acid formation. On blood agar plates clear hemolysis zones surrounded the colonies. On the tenth day of the disease the patient's serum agglutinated the organism completely in a titer of 1:640 in thirty minutes and in a titer of 1:1280 in two hours, with no agglutination in the negative control. Cultures taken on blood, stool and urine were negative. Results of agglutination tests for Malta fever, tularemia and typhoid were negative as was also that of the Kahn test. There were no molds, yeasts or any other organisms found in the lesions at any time.

Subcutaneous injection of 0.1 cc. of a bouillon subculture of the organism into a rabbit produced in twenty-four hours a temperature of 103.6 F. and at the site of inoculation a dark red edematous lesion about 1½ inches in diameter, which the next day was surrounded by a wide dark blue zone. The animal died in forty-eight hours and from the original lesion as well as from the liver, lungs, spleen, kidneys and heart blood *B. violaceus* was recovered in pure and abundant culture.

September 8 X-ray examination showed the chest, lungs and bony framework to be normal. The urine was normal throughout the entire illness.

August 17 erythrocytes numbered 4,032,000 leukocytes 25,000, with 88 per cent neutrophils, hemoglobin 90 per cent

August 26 the erythrocytes numbered 2,832,000, leukocytes 10,600, hemoglobin 55 per cent September 1, erythrocytes numbered 2,310,000, hemoglobin 50 per cent September 8, erythrocytes numbered 2,700,000, leukocytes 10,800, neutrophils 80, hemoglobin 48 per cent

Treatment—In the beginning, it should be noted that the patient had been under treatment for four days before he was seen by us. During this time he had been given 80 grams (5 Gm) of sulfanilamide daily. He had experienced marked gastric and mental upset by the time of his admission to the hospital. It was thought at first that the appearance of the lesions might be due to a chemical change brought about by some local treatment, but such was not the case.

chart shows only two point observations for each twenty-four hour period. All readings were rectal. Within the first week of illness a great deal of abdominal distention occurred, and vomiting was frequent for several days. Simultaneously, large liquid stools appeared which were not of noxious odor and were jet black. Repeated tests for blood gave negative results, and the black stools were never satisfactorily explained. The patient lost weight rapidly and it became evident that his only hope for recovery lay in building up an immunity in the blood stream before he became exhausted physically. The transfusions made a great deal of difference in his appearance and in the clinical course in a short time.

Approximately two weeks after the last temperature chart was made he was having a very slight rise in temperature each day but was feeling well and was allowed to be up. He was

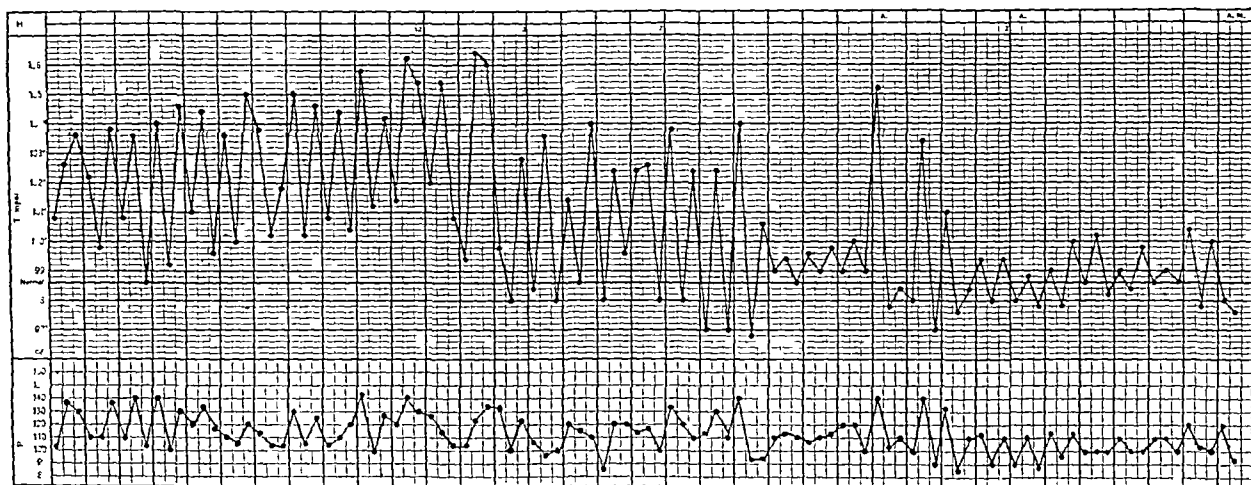

Fig 3—Temperature and pulse

Cultures of material from the local lesions and of the blood were taken. The lesions were thought to be of a mixed type infection due to the pustular ring and the marked cellulitis exhibited on the left arm. Temporarily ointment of ammoniated mercury (U S P) was applied under a gauze dressing over each lesion. After three days a culture was taken from the midst of the ointment covering one of the lesions and the same bacillus was found in pure culture. The lesions were spreading radially from day to day, always accompanied by the peculiar violet color in the skin. At this time it was decided to use wet dressings and a solution of 1/2,000 mercuric iodine was used for several days. The lesions still showed no sign of healing and the culture was still positive for the one organism. Because of some of its cultural characteristics and its pigment formation it was thought that perhaps a wet dressing of an acid solution would be more efficacious. Accordingly, 7 per cent acetic acid was used for a time with the same result.

At about this time the child's condition appeared desperate and since the lesions had shown no tendency to stop spreading and new ones were appearing constantly, it was decided to cleanse all of them and cauterize them with 10 per cent silver nitrate solution. This act caused a great deal of pain but accomplished nothing else. Subsequently freshly prepared dilute solution of sodium hypochlorite was used for a long time. It might be stated that nothing that was used as a local application appeared to inhibit the growth of the organisms or to stop the spreading lesions. Cultures remained positive until they were all healed.

One transfusion of citrated blood (100 cc) was given September 3. This was followed by marked improvement within two days. A second transfusion (250 cc) of citrated blood was given September 11 with a subsequent marked improvement.

Clinical Course—As will be seen in the accompanying chart of temperature and pulse (fig 3), the patient was very ill during most of the course of the disease. The temperature

barely able to stand and walk a few steps and appeared greatly emaciated. The last skin lesion had healed by Oct 26, 1937. The violet pigmentation persisted in the scars of the healed lesions.

THE AMOUNT OF ANTITOXIN USED IN A CASE OF TETANUS

H. A. CABLES, M.D., EAST ST. LOUIS, ILL.

The case reported here is submitted principally because of the amount of antitoxin used but also for some peculiar features of the disease. The report of the case was prepared by Dr. W. H. West, the medical intern, and presented to the staff meeting of St. Mary's Hospital. His report is as follows:

A man, aged 42, American of German descent, a salesman for a plumbing supply company, admitted to the hospital July 2, 1937, complained chiefly of spasms of the muscles of the neck and abdomen. June 28 he was treated by a dentist for alveolar abscess. The patient was unaware of this abscess until the dentist on examination of the teeth a few months previously had diagnosed its presence. At no time had it caused any discomfort. The dentist opened the gums in the upper right side and packed them with surgical dressing (dental). The following day the patient had a mild fever and several chills. These were thought to be due to the alveolar abscess. Four days after the dental surgery was performed the patient noticed an increasing tenseness of the muscles of the neck. June 30 he had two acute spasms tonic in nature, drawing the head posteriorly and lasting from three to four minutes. Their onset was caused by any quick movement. The spasms were not painful. There was inability to open the mouth as normally. The day previous to admission to the hospital he had six such spasms associated with spasms of the upper abdominal muscles.

The patient recalled picking blackberries about June 20, at which time he repaired a flat tire on a dusty road, he had some superficial scratches on his hands at this time.

There were no important points in the past history except that twelve years previously he injured the right eye, the vision of which was lost.

On physical examination July 2, the patient was well developed and had a bronze complexion, he weighed 185 pounds (84 Kg). The palpebral fissures were wide, showing the sclera of the eyes, there was a peculiar smiling appearance, with the teeth visible. The patient was rational cooperative and in no evident pain. The right pupil was small and there was no response to direct light (traumatic cataract). The left pupil was small, with no response to direct light. The facial muscles and the muscles of mastication were found to be slightly rigid. The gums were not tender and the teeth were in excellent condition. The sternomastoid and trapezius muscles were rigid, the head was slightly retracted, it being impossible to flex the head on the chest. There was tenderness inferior to the right mastoid region. The heart and lungs showed no abnormalities. The abdominal muscles above the umbilicus were tense. The genitalia and extremities showed no abnormalities except for a slight mark on the left palm received from a blackberry briar. This was in the outer layer of the skin and showed no signs of inflammation.

Therefore a patient with trismus, opisthotonos, risus sardonicus, rigid abdominal muscles, hyperactive tendon reflexes, abdominal and cremasteric reflexes absent, no paralysis and general hyperesthesia was our subject.

Tetanus and meningitis were thought of, but, with no history of headache combined with the peculiar spasms, meningitis seemed to be ruled out. Twenty-three hours later a spinal tap was done showing the spinal fluid to be under pressure. There was a cell count of 3 and no globulin. The blood count revealed erythrocytes 4,760,000, leukocytes 15,200, hemoglobin 85 per cent, stab cells 13 per cent, segmented cells 63 per cent, lymphocytes 9 per cent and monocytes 3 per cent.

A catheterized specimen of urine was normal and acid. There was no bowel movement for five days after entrance until an enema was given. Twelve hours after admission the patient noticed difficulty in swallowing. He was unable to void for twenty-four hours after entrance at which time he was catheterized. Thereafter no difficulty was experienced.

The patient began receiving tetanus antitoxin on his second day in the hospital, 25,000 units was given every four hours, 15,000 of which was given intramuscularly and 10,000 units intravenously. One hour 2 cc of 25 per cent magnesium sulfate intramuscularly and the next hour 2 grams (0.13 Gm) of soluble phenobarbital subcutaneously were given. This treatment was continued alternating hour by hour. With each serum injection 1 cc of epinephrine hydrochloride was given.

The first four or five days in the hospital, mild transient painful spasms of the abdominal and cervical muscles were experienced about forty-eight or fifty times in twenty-four hours. These were at times from fifteen to twenty minutes apart, lasting from a few seconds to two minutes. At the last the left leg was included in the spasm. Any unusual noise or disturbance would cause onset of spasm. However, after the spasm was over the muscles would relax with the exception of the upper abdominal, facial and cervical muscles. Trismus, risus sardonicus and opisthotonos remained in practically the same degree as on entrance. The inability to swallow increased the second day after entrance until the patient was able to take fluids in only very small amounts without strangling. The third day after entrance this condition gradually improved.

By the seventh day under this treatment the spasms had almost left except for a very occasional one occurring when the patient awakened. Rigidity of abdominal and cervical muscles had decreased and the patient was able to open his mouth somewhat wider. He slept most of the time at this period.

It was decided to give the 25,000 units of antitetanus serum every six hours and to administer the soluble phenobarbital and magnesium sulfate as before. On the eighth day the serum was given every eight hours. This was continued until the

tenth hospital day, when the patient had five spasms, as to those experienced previously. The serum was then injected every six hours.

On the nineteenth day after the first serum was injected he had a temperature of 102.5 F. The next day a scarlatiniform rash began to develop on the cubital region of the left elbow and left gluteal region, where most of the serum had been injected. By the next day this was diffused and "itchy". The rash lasted seven days and would increase in intensity about two hours after a serum injection. The patient felt relief at the application of calamine lotion and the administration of 1 cc of epinephrine subcutaneously.

The last spasm was noticed July 19. The hyperactive reflex gradually decreased after the first week in the hospital, as did as the Babinski reflex, opisthotonos, risus sardonicus and the Kernig reflex.

Thirty days after serum treatment was started, urticaria consisting of blanched wheals that were about 2 cm in diameter occurred. This condition lasted for two days. Epinephrine produced some effect.

Gradually the tetanus antitoxin was decreased. The soluble phenobarbital and magnesium sulfate medication was stopped on the twenty-sixth hospital day. One month after entrance the patient was permitted up in the wheel chair. The tetanus antitoxin was discontinued on the forty-second day and the patient was permitted to go home two days later. He walked out of the hospital. Apparently all rigidity of the muscles had left except a slight restriction of motion of the lower jaw on the right. The patient's weight on dismissal was 175 pounds (79.4 kg). The urine was normal.

Chemical analysis of the blood revealed hemoglobin 80 per cent, leukocytes 6,200, eosinophils 6 per cent, stab cells 6 per cent, segmented cells 65 per cent, lymphocytes 9 per cent and monocytes 2 per cent.

Altogether, the patient received 3,460,000 units of tetanus antitoxin, 700,000 units was given intravenously and 2,760,000 units intramuscularly. This was given over a period of forty-one days. With the modern methods of preparation of tetanus antitoxin it is possible to give large amounts of it without serum sickness, which was caused with the older types of tetanus serum.

It is best to continue serum administration as long as an increased tonus of muscles is present, as shown by the decrease in amount of serum injection in our case and the redevelopment of spasms. This seems to disprove an older idea that tetanus antitoxin given late in the disease does no good. This case presents the problem in which the focus of infection was not found, a chronic release of the tetanus toxin into the bloodstream taking place, the antitoxin being needed to neutralize it. It does not seem probable that the tetanus originated from the opening of the abscesses, because of lack of time of incubation for such an infection as we had.

No ill effects from magnesium sulfate intramuscularly were noted, although the patient received 24 cc of 25 per cent solution intramuscularly for twenty-five consecutive days. The blood pressure fell only 20 mm of mercury during this time.

Therefore it seems advisable to give rest and freedom from any disturbance, maintain nourishment, prolong serum treatment as long as there are any symptoms, and administer sedatives.

First National Bank Building

Probabilities—The smelting of iron ores probably began in southeastern Asia Minor not much later than 1500 B. C. roughly 3400 years ago. Bronze was cast in the same general area at least as early as the beginning of the third millennium before Christ more than 4900 years ago. Copper was reduced from its ores hammered and cast into tools weapons and ornaments for perhaps a thousand years before its alloy, brass, came into use. Thus six thousand years from today take us back to the Stone Age even in those areas where human culture progressed with the greatest speed—Hooton, *E. A. Apes Men and Morons*, New York, G. P. Putnam & Sons, 1930, page 53.

ROCKY MOUNTAIN SPOTTED FEVER

R. R. PARKER, PH.D.

Director, Rocky Mountain Laboratory, United States Public Health Service
HAMILTON, MONT.

(Concluded from page 1188)

The clinical picture varies considerably. On the one extreme are ambulatory patients and abortive attacks and on the other fulminating infections with an early fatal termination. Most infections fall between these two extremes and are of more typical symptomatology, with the case fatality rate varying in different foci. Extremely mild attacks without rash presumably occur, but in such cases a specific diagnosis of spotted fever cannot be otherwise than presumptive.

The usual ambulatory patient has a low fever, the rash is scanty and may be scattered or localized and the patient is not sufficiently ill to remain in bed. The duration is less than two weeks.

Abortive attacks generally have a rather sudden stormy onset with a temperature as high as 104 F and a pulse as high as 130, but the symptoms rapidly lessen in severity and the rash is more or less fleeting. Recovery is complete in from several days to one week.

Patients with a fulminating infection die in from three to five days. They are so highly toxic that the body defenses are literally overwhelmed from the very onset. I have observed that they either have no rash or, if it appears, the spots rapidly coalesce to form large ecchymotic blotches. There is early evidence of the involvement of the central nervous system.

The following description applies to the more typical infections, which are vastly in the majority. If the infection is fatal, death usually occurs between the ninth and the fifteenth day but may be earlier or considerably later.

The incubation period is from two to five days in the more severe infections and from three to fourteen days in the milder ones. There may be a prodromal period of from two to three days or longer, characterized by loss of appetite, irritability and malaise and frequently by chilly sensations. On the other hand, the onset may be sudden and accompanied by some combination of the following symptoms: a distinct chill, marked malaise, sweating, pronounced backache, frontal and occipital headache, injection of the conjunctivae, sensitivity of the eyes to pressure, photophobia, pain in the upper part of the abdomen, pains in the bones and muscles or both (rarely absent), nosebleed, nausea and vomiting. The eyes may appear dull. Delirium, aphasia and lack of coordination of movements are less common. The severity of the symptoms increases more or less rapidly, depending on the virulence of the infecting strain. Chilling may continue. The face soon assumes a typical dusky flush and an apprehensive expression is far from uncommon, particularly when the infection is severe. Often there is a definite body odor. Cyanosis is frequent. The pains in the muscles and bones may diminish with the appearance of the rash. The spleen is enlarged and, if palpable, can often be felt by the third day. Edema, if present, may be generalized but is more frequently limited to the extremities or to the face.

The symptoms most often complained of at the onset are frontal and occipital headache, intense itching in the lumbar region and marked malaise.

The typical rash, which is a manifestation of the specific lesions in the walls of the blood vessels, usually appears on the second, third or fourth day but may be delayed until the fifth or sixth. It is sometimes preceded by a mottled appearance of the skin and is most often observed first on the wrists and ankles and less commonly on the back. Sometimes it is noted next on the forehead. At first it is from pale to bright rose and commonly macular but sometimes papular. If maculopapular it occasionally persists in this form, but it usually becomes macular. It extends rapidly to all or most of the body, including the palms of the hands, the soles of the feet, the scalp and occasionally the eyelids and the mucous membrane of the mouth and throat. It is usually less marked on the abdomen and the face. The color at first disappears on pressure, but later does not, and becomes darker and more or less bluish. The larger and more scattered the spots and the brighter their color remains as the infection progresses, the better the prognosis. Small or pinhead spots that rapidly become darker and more dense indicate a more severe type of infection, and in such cases the rash soon becomes hemorrhagic and more or less confluent and blotchy. When the infection is less severe, successive "crops" of spots are frequently discernible, these crops following each other at intervals of several days. It is not uncommon to receive reports of one two or three crop cases. After recovery, pigmented areas may be left, which become reddish on exposure to heat or cold or on exertion.

The rash is the visible evidence of the specific lesions in the walls of the blood vessels. These lesions are characterized by proliferation of endothelial cells, local necrosis of endothelium and smooth muscle, and thrombosis. In the more severe attacks and in fatal attacks in which death is delayed, there may be resultant sloughing, the parts commonly affected being the scrotum, prepuce, vulva, dependent portions of the body and buttocks. Sometimes the soft palate is involved.

The febrile period is commonly from two to three weeks but may be shorter or longer. After onset, the fever increases at a rate and degree corresponding to the virulence of the infecting strain. In milder infections the rise is slower and the maximum may not be greater than 103 F. In the highly fatal type of infection the temperature rises more rapidly and to a maximum of from 104 to 106. More or less marked morning remissions are the rule. The maximum temperature usually persists into or through the second week. In patients who are recovering the temperature falls by lysis and most often reaches normal about the middle or end of the third week. In patients infected with variabilis strains, lysis is usually accomplished in three or four days, but in those infected with andersoni strains frequently extends over seven or eight days. In fatal attacks there is occasionally terminal hyperpyrexia, the temperature reaching as high as 108.4 F.

The pulse at first is full and strong and the rate in less toxic patients may not exceed 90 beats a minute. In the more toxic patients it tends to become shallow and the rate may range from 110 to 160. A high pulse rate and a high temperature soon after onset are unfavorable signs.

The lungs are usually not involved, but a slight hacking, nonproductive, bronchial cough is typical.

Restlessness and insomnia are among the pronounced symptoms. Hyperesthesia of the skin and neuritis of varying degrees are common. The patient's mind may

than the infection test. If highly fatal strains of passage virus are employed as a source of virus for the protection test, it is essential to use serum virus rather than the whole blood virus. The latter is frequently so potent that definite protective properties of convalescent serum may be overwhelmed and an apparently negative test be secured. It is also important not to use excessive amounts of virus. This test has more value in cases of Rocky Mountain spotted fever than in cases of endemic typhus.

Whenever possible, it is desirable to make both infection and agglutination tests. The protection test is of value under two conditions: first if neither of the other tests has been made and, second, as a check on uncertain results given by one or both of these tests.

The Weil-Felix reaction and the protection test are of no value for testing for past infections. The agglutinin titer for *Proteus* X strains falls rapidly after recovery is complete, and it is a rare patient whose blood serum will show definite virus-neutralizing value a year after illness.

PROPHYLAXIS

Control of the tick carriers of Rocky Mountain spotted fever has not proved feasible except perhaps under highly localized and special conditions. There are therefore but two avenues for preventing infection with Rocky Mountain spotted fever: first, personal care, second, vaccination. Under personal care are included the avoidance of tick bites, the wearing of suitable clothing and the early removal of any ticks which may become attached to the body.

Of course, the best method of avoiding infection is to stay away from known infected areas. This is not possible, however, for a large part of the population in many affected regions. Furthermore, any section in which a tick carrier is present is potentially dangerous, and each year cases are being reported from areas in which the disease was hitherto unsuspected of being endemic.

In regard to suitable clothing there is but one point of first importance, namely, the wearing of apparel that will prevent ticks from attaching to or crawling up the legs. For this purpose high boots, leggings, puttees and socks that are worn over trouser legs are all of real value. The ticks, which usually transfer from vegetation to the clothing at a height of less than 18 inches from the ground, will then crawl up the outside surface of the clothing and most of them can be seen and removed. Those that reach the back of the neck, as many do if not discovered, even if entrance through the clothing has been made at some lower point, will usually be felt when they touch the skin or hairs on the neck. It is good practice when in dangerous country to pass the hand over the back of the neck occasionally to feel for ticks.

Ticks are far more likely to secure a hold on rough clothing than on clothing of smooth texture. Each type of clothing has its advantages, however. The progress of the tick is impeded by the nap of rough cloth, but fewer ticks secure a hold if the cloth is smooth.

Women who go into dangerous areas temporarily for camping or other purposes should whenever feasible wear men's attire similar to that suggested.

If one is continually in tick country, some ticks will reach the body in spite of all precautions. It is necessary therefore that the foregoing measures be supplemented by the examination of the body and the inside of the clothing. Ticks seldom attach at once, and since

they but rarely transfer infection until they have fed for several hours, examinations made twice a day, at noon and on retiring, are usually sufficient. In particularly dangerous areas, however, more frequent examinations are indicated, or, at least, any local irritation should be investigated to determine the cause.

When one retires, all clothing should be removed. This is mentioned because of the common habit among campers and many persons working outdoors of wearing part of the daytime garments at night. Both the body and the clothing should be carefully examined, and the latter should be so placed that any undiscovered ticks are unlikely to crawl from it to the bed. Exceptional care should be used when two persons occupy the same bed. If an infected tick becomes detached from one and attaches to the other, infection of the latter may take place quickly because the virus has already been reactivated. Instances of double infections caused in this manner by a single tick are far from uncommon. In one known instance three persons were thus infected.

Those who are exposed for only a few hours or for part of a day would do well to make a complete change of clothing on reaching the home, and the removed clothing should be so cared for that any unobserved ticks will not be a danger to other members of the household or to other persons.

Clothing placed on the ground attracts ticks from some distance and should be carefully examined before being put on. Ticks will crawl to persons who remain in small circumscribed areas for shorter or longer periods, such as, for example, persons sitting or lying on the ground. Persons sleeping outdoors should use care in selecting a camp or bed site. In this connection, one should bear in mind that ticks are usually more numerous where rodents are more abundant. Such places should be avoided. Within the range of the Rocky Mountain wood tick, one of the safest camping locations is in timber, particularly where low vegetation is scanty, but, on the other hand, open areas in timber may be dangerous. In sagebrush country one should keep away from the sagebrush. Proximity to trails and old roads should be avoided. Particular care should be exercised by persons following trails, since ticks tend to congregate on the vegetation on each side or on the upper side of trails that cross slopes. Grassy strips in the middle of little-used roads and vegetation along road sides are often heavily tick infested.

If a tick is found attached to the body it is best to remove it immediately. This is desirable because every added moment of attachment increases the danger of spotted fever or other tick-borne infection. Many practices have been employed for removal. However the desired result is most easily and quickly accomplished by gently pulling the tick off with the fingers. So far as the ticks that transmit spotted fever are concerned there is little ground for the idea that the mouth parts will thus be left in the wound in spite of popular opinion to the contrary. Better the mouth parts, however, than spotted fever, tularemia or some other equally unattractive infection. However, there is a definite danger of breaking off the mouth parts of ticks which have a longer hypostome, such as, for example, *Ixodes ricinus* *erithromicus*, which is prevalent in parts of the west coast of the United States and Canada and *Amblyomma americanum* common in parts of the South Central and South Atlantic States.

When sterile instruments are at hand, ticks of any species may be removed easily by pulling the tick gently

so as to make a tent of the skin surrounding the site of attachment and then slipping the point of a hypodermic needle or scalpel under the mouth parts. The instrument is then raised, thus removing the mouth parts with a minimum of tissue. However the tick is removed, iodine or some other agent for asepsis should be applied to the site of the bite. A silver nitrate pencil, which can be purchased for ten cents at any drug store, is convenient for outdoor use.

There is no proved satisfactory material which can be placed either on the clothing or on the body to prevent tick attachment.

The United States Public Health Service vaccine for Rocky Mountain spotted fever is prepared at, and distributed from, the Rocky Mountain Laboratory of the National Institute of Health at Hamilton, Mont. So far as it is available, it should be used by those who live in or frequent dangerous areas. Unfortunately this vaccine, which is prepared from the tissues of infected Rocky Mountain wood ticks, is difficult and expensive to produce, and at the present time it is possible to manufacture annually enough for only about 80,000 persons. The cost exceeds \$300 a liter.

This vaccine is used in two 2 cc doses given five days apart either subcutaneously or intramuscularly. For the most part the reaction is local, but in some persons it is constitutional and occasionally severe. Anaphylaxis is rare. The data indicate that the majority of persons are fully protected against the less virulent strains of Rocky Mountain spotted fever but that the average person is only partially protected against the highly fatal type. The maximum degree of protection conferred is retained for less than one year.

During the thirteen years in which the vaccine has been in use fifty-nine persons have been infected the same year in which vaccine was administered. Thirty-three were adults infected in the western Montana area of highly fatal infection (fifteen were laboratory workers, and eighteen were infected spontaneously), three attacks proved fatal, a case fatality rate of 9.09 per cent. During the same period in the same area fifty nonvaccinated adults were infected, thirty-eight died, a case fatality rate of 76 per cent. The fatality rate in this area, therefore, has been approximately 66 per cent lower for the vaccinated group. The remaining twenty-six persons infected the same year in which they were vaccinated acquired infection in areas where the disease is less severe, none died.

In addition to these data there are records of thirty-five cases in which infection took place from one to seven years after vaccination. Of twenty persons infected from one to one and one-third years after vaccination, none died, but three of the remaining fifteen died. They had received vaccine two, three and four years, respectively, before infection. Two of these were infected in western Montana.

The conclusions drawn from the use of this vaccine to date are briefly summarized as follows:

The vaccine has definite protective value. The degree and the duration of protection vary with the person vaccinated and with the degree of virulence of the infecting strain of spotted fever virus.

The average person vaccinated in the spring retains marked immunity during at least the remainder of that year. The immunity is usually sufficient to afford full protection against the relatively mild strains of spotted fever but is apparently progressively less effective as the virulence of infecting strains is increased. Regarding the highly fatal type the data suggest that most

children are fully protected but only occasional adults. In the majority of the latter, however, protection is sufficient to ameliorate markedly the usual severe course of infection and to insure recovery. Hospitalization and nursing care are decided aids to persons in whom there seems to be a delicate balance between the degree of protection conferred and the aggressiveness of the infecting strain.

If a person is infected during a period beginning several days after the first injection but before the full degree of immunity has developed after the second or third, there is a strong probability that the subsequent clinical course of the disease will be affected favorably, even in areas of high case fatality rate.

In areas where relatively mild infections prevail and the incubation period is prolonged, the administration of vaccine as soon as possible after tick bite may ameliorate an impending infection. This appears particularly probable in the case of persons who have been vaccinated in one or more previous years. The procedure is not recommended in areas of highly fatal infections where the incubation period is short unless the person has been previously vaccinated.

It now seems probable that a considerable percentage of vaccinated persons carry a greater or less degree of immunity over into the second year even against highly virulent strains. The degree of this residual immunity appears to be greater in persons who have been vaccinated two or more successive years. The evidence as to whether any immunity is carried beyond the second year is less definite. Until further and more definite data are available, it is necessary to recommend that vaccination of exposed persons be repeated each year.

Of persons vaccinated and infected the same year, those who have received vaccine two or more successive years appear to have greater resistance than those who have received vaccine only one year. The usual dose can probably be halved for persons who have been vaccinated at least three successive years.

CONCLUSION

Rocky Mountain spotted fever is only one of several tick-borne diseases endemic in North America. Tularemia is widespread in the United States and has been recognized in several widely separated points in Canada. It is transmitted to man by both the Rocky Mountain wood tick and the American dog tick, perhaps by *Ixodes ricinus californicus* along the Pacific coast, and by other means. In nature it is carried by the rabbit tick and probably by the bird tick, *H. cinabarina*. The last species infests only birds. Several other species have been shown to be potential carriers.

Tick paralysis is a more localized problem and is reported sporadically from parts of Oregon, Washington, Idaho and Montana but is perhaps most prevalent in southeastern British Columbia. Rare cases occur in Wyoming. As far as known, it is caused only by the female Rocky Mountain wood tick.

Colorado tick fever is another disease transmitted by the Rocky Mountain wood tick. It has been reported most often from Colorado and Wyoming but is present also in Utah and Idaho and probably has an even wider occurrence. Suggestive cases have been reported from California.

Relapsing fever is now known to be endemic in several Western states and in southeastern British Columbia and, like Colorado tick fever, will probably be found to have an even wider distribution. At least two ticks of the genus *Ornithodoros*, *turicata* and *hermsi*, are involved in its transmission.

A new filter-passing agent, recently found in the Rocky Mountain wood tick by Dr. Gordon E. Davis and Dr. Herald R. Cox of the Hamilton Laboratory, has still more recently been identified in *Dermacentor occidentalis* in southwestern Oregon and in California. It unquestionably causes a rodent disease and possibly one to which man is susceptible. It may be represented by some of the numerous unidentified disease conditions reported each year as following tick bite, in fact, three suspicious infections have recently been observed.

Secondary infections may occur as a result of the bites of the ticks thus far mentioned as well as of others. These sometimes result in chronic lesions, septicemia, loss of limb or, occasionally, death.

These other disease conditions tick borne and caused by tick bite have been briefly referred to because many of the observations concerning them have been made within relatively recent years and because, along with the data relating to Rocky Mountain spotted fever, they show that there is in North America a general tick and disease problem of widening scope geographically, from the standpoint of disease entities, and regarding the number of species of ticks involved.

This problem is most serious in the West where topography, climate and the limitations otherwise imposed on economic development have favored the persistence of essentially natural floral and faunal conditions over vast areas. These in turn have fostered, and will likely continue to foster, the maintenance and perpetuation not only of such diseases of nature as those herein discussed but also of considerable populations of the ticks and the other parasites which transmit them to man.

RIBOFLAVIN

DIETARY SOURCES AND REQUIREMENTS

HENRY C. SHERMAN, Ph.D., D.Sc.

AND

CAROLINE SHERMAN LANFORD, Ph.D.

NEW YORK

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. The articles will be published later in book form.—Ed.

At the time of the preceding symposium in 1932, the terms vitamin B₂ and G were used synonymously by Sure¹ as standing for the more heat stable part of the vitamin B complex, and Underhill² wrote of vitamin G deficiency as "intimately associated with the complex syndrome of symptoms included under the term pellagra." At the time of the present writing (the summer of 1937) the evidence appears conclusive that there are at least three relatively heat stable substances in the vitamin B complex: (1) riboflavin, (2) vitamin B₁₂, and (3) another substance which perhaps may be considered P-P or the Goldberger pellagra-preventive substance which may or may not be the same as the substance which prevents blacktongue in dogs. (It is also held by some careful students that

more than one substance may be involved in the nutritional problem of human pellagra, even when this is distinguished from all so-called pellagra-like disorders in other species.)

Riboflavin and vitamin B₆ are both required for growth and for the maintenance of health in the rat and probably in mammals generally, including man. The fact that we do not know any specific human disease due to shortage of riboflavin is entirely compatible with the view that this substance is important in human nutrition. A detailed discussion of reasons for believing that riboflavin plays a role in the life process of the human as of other species would probably seem superfluous to a majority of readers at this date, and to a still larger majority in the future. Suffice it to point out that our species has evolved in the direction not of shortening the list of things it needs but of lengthening the list of things it can use to advantage.

Shortage of riboflavin stunts the growth of the young and at any age causes a lowering of general tone and a condition of premature aging or unwholesomeness of the skin, with loss of hair. The skin condition has sometimes been called a "nonspecific" dermatitis or dermatosis as distinguished from the "florid" dermatitis of vitamin B₆ deficiency.³

The substance here called riboflavin was first described as lactoflavin (previously called lactochrome)⁴. Ovocflavin and hepatoflavin, first so named for the materials from which they were prepared, were soon found to be chemically identical with lactoflavin.

The same substance has also been reported as isolated from several other sources as widely separated biologically as the milk of different species, muscle, liver, kidney, eggs, fish eyes, malt, grass, dandelion flowers, and both marine and fresh water algae as typified by *Fucus vesiculosus* and *Cladophora suteri* (Karrer, Heilbron, Parry and Phipers⁶).

DIETARY SOURCES OF RIBOFLAVIN

Corresponding with the wide biologic distribution of riboflavin in the plant and animal kingdoms as just mentioned, it is found more generally present in significant amounts among varied food materials than is vitamin A but less abundant in the seeds which form so large a part of man's food than is vitamin B₁. It is doubtless true, as suggested by Eusterman and Wilbur in the previous symposium, "that certain individuals, the poor in particular, do not consume enough foods that contain [significant amounts of] vitamin A and vitamin G to insure a state of nutrition essential to the greatest physical stamina, efficiency and ability to resist infectious diseases." In fact, this view is strongly reinforced by the experimental finding⁶ that the optimal intake of vitamin G (riboflavin) is very much (probably at least fourfold) higher than is easily demonstrable as strictly necessary.

The relative amounts of riboflavin in foods are therefore a matter of importance to health and should be given weight in present-day considerations of food values and planning of the dietary.

From longer lists published elsewhere⁹ and from data reported by Daniel and Munsell¹⁰ we selected for table 1 some typical foods, including those which have thus far been most thoroughly studied in this respect.¹¹ Some of these deserve additional brief comment.

TABLE 1—Approximate Riboflavin Values of Certain Foods*

| | Units† per 100 Gm |
|--------------------------|-------------------|
| Apples | 10 to 43 |
| Bananas | 26 to 50 |
| Beef lean | 90 to 150 |
| Carrots | 30 to 75 |
| Carrot tops | 200 |
| Cheese | 44 to 288 |
| Cottonseed flour or meal | 150 to 300 |
| Eggs | 99 to 150 |
| Egg white | 60 to 120 |
| Egg yolk | 150 to 300 |
| Kale | 140 to 260 |
| Liver | 800 to 1900 |
| Milk | 34 to 100 |
| Oranges | 15 to 65 |
| Potatoes | 15 to 31 |
| Spinach | 100 to 175 |
| Tomatoes | 12 to 25 |
| Turnips | 17 to 50 |
| Turnip green | 300 |
| Wheat entire | 48 to 124 |
| Wheat germ | 150 to 404 |
| Wheat dry | 750 to 2500 |

* Selected from among the data on pages 415 to 417 of Sherman's *Chemistry of Food and Nutrition* ed. 5 1937 from Daniel and Munsell¹⁰ and from Levine and Remington.¹¹

† These units are Sherman-Bourquin units of vitamin G determined by the rat growth method of Bourquin and Sherman¹² and of Page¹³ as more fully explained below.

Riboflavin appears to be formed primarily in the green leaves of actively growing plants and to remain there in higher concentration than elsewhere in the plant. Thus, of the three tissues constituting the edible portion of broccoli, the flower buds contain only a little over half as much riboflavin as the leaves, and the twigs still less. Similarly, carrot tops show something like four times the riboflavin value of the roots. This concentration of riboflavin in the green leaves where it is formed presents an interesting contrast to the transfer of carotene from leaf to root which occurs in the carrot.

There are indications that, as the leaves mature and dry, there may be a considerable diminution in their riboflavin value. Correspondingly it was found at the Ohio Agricultural Experiment Station¹⁴ that milk from cows receiving an abundance of fresh young grass tended to be slightly richer in riboflavin than the milk of cows fed drier and more mature grass, but in milk as ordinarily produced under present-day conditions of dairy farming seasonal variations of vitamin value are much smaller than would be inferred from many of the statements in the literature. Perhaps the best present evidence in this case is expressed in the figures of the seventeen comparable quantitative results of ten independent investigations. These show an average of 67 ± 3 Bourquin-Sherman¹⁵ units of riboflavin per hundred grams of milk, with a coefficient of variation of 28, which is a lesser variability than would perhaps have been expected. Nor should there be any serious

diminution of the riboflavin value of milk in pasteurization or in preservation by drying or by condensation (partial evaporation) and canning. Milk is thus a relatively stable and dependable source of riboflavin and will almost always be the chief source in the dietaries of children because of the prominence that should be given to milk in the dietary for other nutritional reasons as well. In any long view of food economics there is also the consideration that milk is a food crop the production of which can be greatly increased in response to consumer demand, with little if any increase in cost per unit to the consumer.

A contrasting case in this respect is that of liver, the supply of which can be increased only by rearing and slaughtering whole animals of which the liver is only a very minor part. Hence (as Minot, if we remember correctly, has complained) any emphasis on liver as a food for people in general has the unfortunate result of increase in its cost to those who really need it.

Gyorgy¹⁴ has made semiquantitative comparisons of the riboflavin values of some different flesh foods. He finds fish muscle a poor source of riboflavin, compared with beef and chicken muscle, which he finds to contain about equal concentrations. The red leg muscle of chicken appeared to contain slightly more than the white breast muscle, but this difference does not appear sufficient to justify discrimination in a practical consideration of dietary sources. In Gyorgy's experiments, beef liver appeared about fifteenfold richer than beef muscle, while in the apparently more precise experiments of Day¹⁶ and of Munsell¹⁰ liver showed about tenfold higher riboflavin value than did an equal weight of muscle.

Rose and Phipard¹⁶ recently found that fresh raw peas and lima beans contain about 100 units of riboflavin per hundred grams and observed no loss in

TABLE 2—Relative Prominence of Certain Types of Food (in Dietaries Costing from \$2.38 to \$3 Weekly per Food-Cost Unit)

| Food or Food Group | Per Cent of Food Money Allocated | Percentages Contributed by Each Food Group to the Total Secured | | | | | |
|---------------------------------------|----------------------------------|---|---------|-------|------------|------------|------------|
| | | Cereals | Protein | Calum | Vita min A | Vita min C | Riboflavin |
| Meats and fish | 25.5 | 12.9 | 36.2 | 2.7 | 7.1 | 0.7 | 32.2 |
| Eggs | 5.0 | 1.7 | 4.9 | 2.7 | 6.0 | — | 5.3 |
| Milk, cheese, ice cream | 12.1 | 9.8 | 16.0 | 60.7 | 13.0 | 3.3 | 34.2 |
| Butter, cream | 7.6 | 9.3 | 0.4 | 1.4 | 16.0 | — | 0.4 |
| Other fats | 3.0 | 7.8 | 0.5 | 0.1 | 0.8 | — | 1.1 |
| Breadstuffs, cereals, bakery products | 17.6 | 30.3 | 27.3 | 12.0 | 3.5 | 0.6 | 5.7 |
| Sugar, sweets | 4.2 | 12.4 | 0.1 | 2.1 | — | — | — |
| Potatoes, sweet potatoes | 1.5 | 3.8 | 4.4 | 3.4 | 2.6 | 22.8 | 7.2 |
| Dried legumes, nuts | 1.8 | 2.9 | 5.3 | 3.4 | 0.2 | — | 0.8 |
| Tomatoes | 1.5 | 0.3 | 0.4 | 0.5 | 0.5 | 7.8 | 0.6 |
| Citrus fruits | 3.2 | 1.1 | 0.5 | 3.0 | 0.6 | 29.6 | 2.3 |
| Green and yellow vegetables | 3.9 | 0.8 | 1.4 | 3.4 | 37.7 | 12.8 | 3.7 |
| Other vegetables | 7.4 | 1.0 | 1.0 | 2.8 | 1.3 | 8.1 | 1.2 |
| Other fruits | 3.9 | 2.8 | 0.7 | 1.4 | 4.0 | 12.3 | 3.9 |

* Adapted from Stebeling.¹⁷

either cooking or freezing. In mature seeds of both kinds there appeared to be little diminution in vitamin G (riboflavin) value as compared with the fresh seeds. Pea seedlings showed an increase in riboflavin content over the seeds from which they were sprouted.

¹³ Bourquin, Anne and Sherman, H. C. Quantitative Determination of Vitamin G. *J. Am. Chem. Soc.* 59: 501 (Sept.) 1937.

In practice, the actual importance of any given food as a dietary source of riboflavin (or of any other specific nutrient) depends of course not only on the concentration of the substance in the food but also on the place (or quantitative prominence) of the food in the dietary or food supply. Stiebeling¹⁷ has ascertained the relative place of different dietary articles in food budgets and has computed what proportion each contributes of the total of each of several nutrients thus secured. The data for riboflavin and some of the other nutrients are given in abbreviated form in table 2.

It seems sufficiently established that the Bourquin-Sherman method for the measurement of "vitamin G values" measures riboflavin rather than any other factor—and consistently so when the method is carried out strictly as described by its authors. This has been found independently by several users of the method but, of course, should not be assumed for any cases in which the method is modified, especially as to the preparation and use of the 80 per cent alcohol extract of wheat as a source of vitamin B₁, B₆ and any still unknown "B factors" needed by the rat. Even when the Bourquin-Sherman directions are explicitly followed, the adequacy of the extract to this purpose should be tested by each laboratory on the materials (and test animals) which it uses, for the vitamin B₆ value of wheat is reported to be subject to wide variation as tested in different parts of the world.¹⁸ The amount of riboflavin which the Bourquin-Sherman "unit of vitamin G" represents has been estimated as from about 3 to 5 micrograms. The chief causes of this variation, so far as present knowledge suggests, are (1) differences in purity of previously available preparations of riboflavin, (2) variations of riboflavin requirements with the size of the test animal, (3) completeness of prevention of coprophagy,¹⁹ and (4) the possible influence of some less well defined difference in the nutritional background of the test animal or in the bacteriology of its environment which may influence the precise amount of riboflavin needed or absorbed with a given diet, even when all mechanical precautions for prevention of coprophagy are observed.

DIETARY REQUIREMENT FOR RIBOFLAVIN

As yet, estimates of the amounts of riboflavin required for normal human nutrition are necessarily matters of judgment rather than of actual direct measurement. The independent judgments of Rose²⁰ and of Stiebeling²¹ are in substantial agreement and are probably the most influential estimates thus far available. Rose has suggested for children up to 10 years of age at least 400 units a day in all cases, or 20 units per hundred calories if more than 2,000 calories a day is consumed, for adults 20 units per hundred calories. The recommendation of Stiebeling is 450 units for boys under 6 and girls under 7 years of age 540 units for boys from 7 to 10 and girls from 8 to 13 years of age and 600 units for older children and adults, or 570 units per capita of the population.

How far above these allowances the actual optimum will be found is a question for the future.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE
HOWARD A. CARTER, Secretary

THE PRESENT STATUS OF SHORT WAVE DIATHERMY

FRANK H. KRUSEN, M.D.

ROCHESTER, MINN.

About two and a half years ago, in a preliminary report for the Council on Physical Therapy, I¹ pointed out that, with further clinical investigation, short wave diathermy might prove to be a useful therapeutic agent. Sufficient additional data are now available to warrant a further report. From the published mass of conflicting opinions, one may now winnow enough information to draw a number of additional conclusions.

DEFINITION

Short wave diathermy may be defined as the therapeutic heating of the bodily tissues by means of an oscillating electric current of extremely high frequency (from 10,000,000 cycles per second and a 30 meter wavelength to 100,000,000 cycles per second and a 3 meter wavelength).

NOMENCLATURE

A confusing variety of terms have been suggested to describe such radiation, among them being "short wave therapy" and "ultra-short wave therapy" (Schliephake²), "radiotherapy" (Bierman³), "radiotherapy" (Kobak⁴), "parathermy" (Turrell⁵), "neo diathermy," "short diathermy" and "ultra-diathermy" (Nagelschmidt⁶), "short" and "ultra-short wave diathermy" and "short wave diathermy." Although there is merit in a number of these designations, the one last mentioned, "short wave diathermy," has been generally considered in the United States as being most acceptable, since these waves are short only in juxtaposition to conventional diathermy and since they may probably be best considered as another form of diathermy. The Council on Physical Therapy considers "short wave diathermy" acceptable terminology.

HISTORY

D'Arsonval's⁷ presentation of his experimental data to the Académie des sciences in 1892 constituted the first basis for the application of high frequency currents in medicine. Following the development by De Forest of the triode principle of electronic oscillations,⁸ the studies of Gosset and his co-workers⁹ in 1924 are considered to be the first scientific investigation of the effect of the oscillating field on living cells. The studies of Schereschewsky¹⁰ (1926) in this country, indicating a specific lethal action of short wave diathermy, later appeared to be disproved by the investigations in 1929 of Christie and Loomis¹¹ and by those of Kahler and his co-workers¹². Still later, following Whitney's work at Schenectady, Bork and his co-workers¹³ began their outstanding studies which led to the use in the United States of short wave diathermy for the production of therapeutic fevers¹⁴.

Meanwhile in Germany Esau¹⁵ was beginning studies in 1925 which caused Schliephake¹⁶ to credit

Owing to lack of space this article has been abbreviated here by omission of the bibliographic references. The complete article will be available in the reprint.

2 If the wavelength is less than 12 meter, the "ultra" prefix is used.

him with having first introduced short wave diathermy devices of sufficient power for satisfactory therapeutics Patzold¹⁹ likewise is credited by German writers²⁰ with having made important contributions on the physics of short wave diathermy

Unfortunately, these early studies were followed by many pseudoscientific, hyperenthusiastic presentations Kovacs²¹ decried the fact that many investigators rushed into print with premature conclusions, and Eidinow²² pointed out that many workers, in their zeal, had made observations which could not be confirmed

APPARATUS

The appliance for the production of short wave diathermy fields resembles in construction a short wave radio transmitter, with the exception that the electrical energy, instead of being dispersed from antennas as in broadcasting, is mostly confined between condenser plates to produce an electric field, or within a coil to produce an electromagnetic field

Bodily tissues, acting partly as conductors and partly as dielectors when placed within these fields, are allegedly heated by the production of ionic oscillations and molecular friction. Power losses occur. The entire phenomenon, therefore, is customarily designated as "hysteresis." DeWalt²³ has suggested a simple simile to illustrate the manner of heating of dielectrics by short wave diathermy. He stated that the rubbing of a rubber band with the fingers produced heating of it by surface friction and that this might be compared to the heating produced by a current flowing through a substance which offered ohmic resistance. On the other hand, if one should hold the rubber band at the ends and stretch it back and forth, heat would be produced by molecular friction inside the band. This result may be compared to the effect taking place when a high frequency field produces molecular friction and heat losses within a substance which acts as a dielectric.

Two types of apparatus are commonly used, the vacuum tube (or valve) machine and the spark gap device.²⁴ Holzer and Weissenberg²⁵ have described a third type, an inexpensive "low output generator," which Weissenberg²⁵ used for "low intensity treatments", however, I am inclined to agree with Taylor,²⁶ who said it seemed that the so-called low energy apparatus could have "no effect other than a psychological one." The consensus seems to be that short wave diathermy machines, to be effective, should have a fairly high output in watts.

Vacuum Tube vs Spark Gap Apparatus—There is much disagreement concerning the relative effectiveness of vacuum tube and spark gap machines. Speeding²⁷ felt that spark gap machines were inefficient, and Wilson²⁸ believed that they possessed a definitely restricted field of action. Holzer²⁹ said their voltage curves varied considerably and that precise indication of wave length was impossible. Christie²⁹ said that they had been made practically obsolete by the vacuum tube machine and that for the same degree of heat the damped currents produced higher instantaneous voltages which favored the production of burns. On the other hand the undamped current was smooth and continuous and had a minimum tendency toward sparking. From the opposite point of view, when properly constructed a spark gap apparatus may be very effective. Bierman³⁰ has used one with considerable satisfaction. Likewise Webster³¹ felt that Wilson's criticism of the spark gap machine was unjustified and premature, since he had used one with gratifying results. Although after several years of trial of a

number of these machines, I have had more technical difficulties with them than with tube appliances, I am not prepared to condemn them as unsatisfactory. One may conclude, nevertheless, that most observers prefer the tube apparatus.

SHORT WAVE DIATHERMY VS CONVENTIONAL DIATHERMY

In support of the superiority of short wave diathermy over conventional diathermy, it has been said that the former would produce more intense, less hazardous local heat (Davis³²), that it penetrated certain bodily layers, which were avoided by conventional diathermy (Schliephake³³), that it had a greater range of flexibility and more profound physiologic action (Kobak³⁴), that it was more efficient and rapid in action (Wilson³⁵), and that, although diseases rationally treated by heat respond as well to conventional diathermy when the lesions are superficial, deeply situated parts in the thorax and abdomen are better heated by short wave diathermy (Cumberbatch³⁶). Wilson³⁷ reached the questionable conclusion that short wave diathermy was effective in treating suppurative lesions, whereas conventional diathermy was dangerous. Taylor²⁶ felt that short wave diathermy had the advantages of a deeper heating effect and avoidance of high field concentration around the electrode.

Egan³⁸ said that short wave diathermy should not be considered as modified conventional diathermy. Speeding²⁷ stated it as his belief that the effects of the former were not identical with those of the latter. On the other hand, d'Arsonval has been quoted⁹ as saying that "there is no wall separating diathermy from short waves." Nagelschmidt⁸ pointed out that there were no sudden marked differences in the effects produced by radiations of nearly related wave lengths in other portions of the spectrum, and that none could be expected in this instance. Furthermore, Kovacs²¹ stated that, since there was no essential difference between the primary physical effects of the two, one could not expect much difference in their physiologic and therapeutic effects. He felt that short wave diathermy was more convenient to use but that the lack of a proper method of determining dosage was a distinct disadvantage. Kowarschik³⁹ reported (1933) comparisons of the effects of these two methods on cadavers, which experiments led him to state that it was wrong to assume that short wave diathermy produced relatively greater heating than conventional diathermy. His more recent studies⁴⁰ indicate that he credits short wave diathermy with many favorable effects.

Turrell⁴¹ was not of the opinion that short wave diathermy produced improved or increased thermal action as compared with conventional diathermy. Schmidt⁴² felt it was unlikely that the former would replace the latter. Eidinow⁴³ found no results with short wave diathermy which could not be produced by conventional diathermy. Hollender⁴⁴ said that no more could be claimed for short wave diathermy than for conventional diathermy, with either there was simply heat production but in the case of the former there was deeper penetration and more facility of application. Clinically I have observed no particular difference in the effects produced, but I have been pleased with the convenience of short wave diathermy. The consensus seems to be that there is no great difference in the effects produced by these two forms of diathermy, but that short wave diathermy produces deeper, more uni-

form heating and is more readily applied, although dosage control is more difficult than with conventional diathermy

PHYSICAL EFFECTS OF SHORT WAVE DIATHERMY

Selective Heating—There has been much disagreement concerning the problem of selective heating by short wave diathermy. It is frequently stated that certain selective "point heating" effects can be demonstrated *in vitro*. Esau's⁴⁴ often described experiment on alkalized water shaken with liquid petrolatum is a typical example. When this emulsion was placed in a condenser field, the temperature increased and it finally began to steam, indicating that the water had "been heated to 100 C" although the temperature of the entire solution was only 60 to 70 C.³⁴ Whitney's⁴⁵ heating of tadpoles in distilled water, which remained comparatively cool is presented as another example of selective heating. Selective heating of non-living substances has been demonstrated by Schliephake,⁴⁷ Mortimer⁴⁸ and Bachem.⁴⁹ Using such examples, enthusiasts have contended that marked *in vivo* selective heating effects on various bodily structures can be effected by proper selection of wave length.

Starting with the studies in 1931 of McLennan,⁵⁰ who theorized that, if the dielectric constants of various parts of the body were different, "heating of one member" might be favored by proper orientation, various claims have been advanced.

Schliephake,⁴⁷ for example, contended that a unique property of ultra-short waves was their selective thermal action and that it was possible that some parts of tissues—for example, cells, intercellular substances, nuclei and protoplasm—might be affected in different degrees according to their composition. Breitweiser⁵² said that there existed, for each combination of wave length and dielectric constant, a particular resistance for which the heating would be a maximum. Bierman and Schwarzschild³⁰ pointed out that, with the exception of fat, all human tissue has practically the same dielectric constant. They felt that there was a tendency for more uniform heating at higher frequencies but that it was possible to heat a certain type of tissue more than others.

Pratt and Sheard,⁵³ concluded that, in the living animal, tissues are heated to different degrees by the systemic application of the short wave electric field. (It has been suggested, however, that their use of thermocouples in the field may have produced the variations noted.)

Mortimer's⁴⁸ studies indicated that, in live anesthetized dogs with the viscera exposed, the different organs heated up at approximately the same rate, the blood serving as a very efficient distributing mechanism, whereas, in dead dogs, different organs heated at different rates. Bierman⁴ questioned the occurrence of selective heating in the living animal, and Chaffee²⁹ believed that the circulation of blood was a powerful agency toward equalizing the bodily temperature. Wolf⁵⁴ said substances with different dielectric constants obviously were heated to different degrees, but that, in the living human being, the slight variations in dielectric constants were equalized by the circulation. Coulter and Osborne⁵⁵ said that a selective heat production could readily be demonstrated in inorganic substances and dead tissues, but that in the living animal, owing to dissipation of heat by an efficient circulation, no selective heating could be expected. Kovacs²¹ Eidinow,⁵⁶ and Mortimer and Osborne⁵⁷

expressed similar negative views with regard to the possibility of selective heating in living tissues.

Coulter and Osborne⁵⁵ demonstrated by means of pelvic heating experiments a lack of specific heating for various wavelengths. From a clinical standpoint I have observed no obvious selective heating effects. The consensus would seem to have been well expressed in a recent report of the Council on Physical Therapy⁵⁸ that, so far as competent investigators have been able to determine, there is no demonstrable selective thermal action in the living body.

Thermopenetration—With regard to penetration of heat during applications of short wave diathermy, marked differences of opinion have been noted. Schliephake⁴⁸ claimed that heating took place "from within outward" and that there was superior penetration with short wave diathermy. Bierman and Schwarzschild³⁰ claimed more uniform heating with higher than with lower frequencies. Patzold⁵⁹ believed that, with the uniform field distribution made possible by higher frequency and wider air gaps between electrodes and bodily surface, the temperature in the interior of the body and at the surface could be "of equal magnitude." Reiter⁶⁰ said that, with short wave diathermy, deep heating could be produced as a result of dielectrical losses deep within the body. Pratt and Sheard⁶¹ concluded that the relationship of deep heat to surface heat was dependent on the distance at which the condenser plates were placed with respect to the surface. With more air space, deep heat was greater than superficial heat, whereas with less air space the reverse was true.

Mortimer and Osborne,⁵⁶ however, reported a thermal gradient from hot skin to less hot tissues within and concluded that there was no evidence that short wave diathermy possessed more uniform penetration of heat into the body than conventional diathermy. Kobak⁶² felt that the differences between the observations of Pratt and Sheard and those of Mortimer and Osborne were due to differences in the methods of spacing between electrodes and the body surface.

While laboratory studies have elicited conflicting views, many clinical observations have indicated failure of deep heating with short wave diathermy. Thus, Schultze-Rhonhof and Rech⁶³ applied short wave diathermy electrodes to the pelvis, front and back, and concluded that there was no pronounced increase of internal temperature, as measured by alcohol thermometers, although a noticeable heating of the skin was observed. Coulter and Osborne⁵⁵ confirmed these observations, concluding that the surface tissues could not tolerate the excessive heating necessary to produce adequate deep heating. Cumberbatch³⁶ also reported that he could not heat the interior of the pelvis with external applications of short wave diathermy. I have found, however, that, in conjunction with fever therapy, it is possible to raise the internal temperatures of the pelvis several degrees by applying short wave diathermy with a bare metal vaginal electrode, as described by Horowitz and his co-workers.⁶⁴

Eidinow⁵⁶ said that the greatest heating appeared to be centered in the fatty tissues and Chaffee²⁹ wrote that, while the so-called cutaneous effect was negligible when the body was the conductor nevertheless it was fairly well established that the surface of the body was more intensely heated than the interior.

My clinical observations show very little difference between the heating effects of conventional and of short wave diathermy.

The consensus would seem to be that for various physical reasons short wave diathermy should produce more uniform and deeper heat penetration than conventional diathermy. But for reasons which at present must be purely a matter of conjecture, many clinical observations have not confirmed this opinion.

Wavelengths—Various observers are in marked disagreement concerning the possibility of the production of diverse effects by different wavelengths between 3 and 30 meters. For example McLennan⁵⁰ thought that, by choice of wavelength, heating of portions of the body having a certain conductivity might be favored. Schliephake¹⁸ claimed that "unpleasant sensations" were produced sooner by 3 meter waves than by 7 meter waves, and he said also⁶⁴ that staphylococci were killed in the condenser field at different rates of speed according to wavelength. He also affirmed⁶⁵ that if with a wave of 4 meters the muscle was heated more and the fat less, with another wavelength the fat might be heated more than the muscle. Liebesny⁶⁵ said that with 4 meter waves he had cured actinomycosis in two cases in which the condition had been unaffected by waves of 15 meters. Reiter⁶⁶ believed there existed for every tissue an optimal wavelength, and he also said⁶⁶ that, with equal primary energies, one ought to get the most heat with the shortest wavelength. Bierman and Schwaizschild⁵⁰ contended that it was possible by proper selection of frequency (or wavelength) to heat one type of tissue at the expense of another, and that a frequency of 30,000,000 cycles per second heated lung tissue most, whereas a frequency of 75,000,000 cycles heated cartilaginous tissue most.⁶⁷ Breitweiser⁵² said that selective effects were more pronounced with ultrashort waves. Kobak⁶⁸ was of the opinion that the best clinical results were obtained with apparatus of high wattage output in an ultrashort wave range. Gale⁶⁹ believed the question of optimal wavelength was not settled yet.

On the other hand, Nagelschmidt⁸ said that there was never a sudden change of the effects of adjacent wavelengths within the entire range of diathermy, and further that,⁷⁰ clinically, there was no tangible demonstration of specificity of wavelengths in the living body. Turrell⁴¹ doubted that certain wavelengths had selective properties for certain cells. Speeding⁷¹ felt that there was no special value in very short wavelengths (6 meters or less). Wolf⁷⁴ said that opinion tended more and more to the conclusion that no specific effect is produced by any particular wavelength. Furthermore, Kovacs⁷² averied that claims for specific effects by certain wavelengths had not found general corroboration. Chaffee²⁹ said that he was sure of his position in stating that no specific effect of any particular frequency had been proved to exist, nor was this to be expected, since the highest frequencies used were far too low to elicit any specific molecular activities.

While most of the foregoing observations have been based largely on conjecture, certain definite studies have been made by actual experiment. Thus Hill⁷ in experiments on rats found that there were no differences in certain effects on experimental tumors whether the wavelengths employed were 3-4 meters, 6 meters

or longer. Mortimer and Beard⁷³ tested by actual experiment fourteen short wave diathermy machines, of wavelengths between 6 and 25 meters, and they concluded that, for heating purposes, there appeared to be no advantage of any one wavelength over another. Coulter and Osborne⁷⁴ found no significant differences in heating effects of various wavelengths (9, 15, 16.4 and 24 meters) in pelvic heating experiments. Horowitz and his co-workers⁶³ used nine different machines with wavelengths varying from 6 to 18 meters in pelvic heating experiments and agreed with the results of Coulter and Osborne.⁶³ Coulter and Carter⁷⁵ reported that studies on the heating of live human muscle and fat revealed no significant heating differences with the use of various wavelengths (6, 12, 18 and 24 meters). Coulter and Osborne,⁷⁶ in additional studies on the heating of live human muscle and fat, with diverse wavelengths of short wave diathermy (6, 12, 18 and 24 meters) observed no noteworthy differences in the amount of heating. It is noted however, that an editorial in the *Archives of Physical Therapy* expressed the opinion that the studies of Coulter and Osborne⁷⁵ indicated, despite their conclusions, that shorter wavelengths produced greater heating in the muscular than in the subcutaneous regions.

In my opinion these differences are so slight that I agree with the authors that they are negligible. My own clinical observations lead me to agree with Kobak⁶⁸ that an apparatus of high wattage output gives the best clinical results, however, I have seen no particular advantage in the use of the shorter wavelengths. The consensus (particularly of those who have performed careful experiments) would seem to be that the effect of various wavelengths between 3 and 30 meters is approximately the same.

BACTERIOLOGIC EFFECTS

Certain specific actions on bacteria and their toxins, both *in vitro* and *in vivo*, have been claimed. Szymanowski and Hicks⁷⁶ performed experiments on the effect of short waves on bacterial toxins. They mentioned that the effects might be due to "a specific local heating of the toxic molecular complex" but concluded that "ultra high-frequency radiation under the conditions described is capable of producing definite attenuation of the three major bacterial toxins, diphtheria, tetanus and botulinus, in raw broth filtrates. This effect is obtained without the development in the toxin of temperatures that would themselves affect the potency of the toxin." In later studies, however, Hicks and Szymanowski⁷⁷ changed their opinion and stated after further experimentation that "the results tend to establish that ultra high frequency radiation, at least under many conditions, is biologically active only through the heat induced" and that there was "no evidence, so far, to show that there is any factor of significance in exposure to high frequency fields except that of heat."

Schliephake's⁶⁴ claim of having killed staphylococci at varying speeds with different wavelengths has been mentioned, as has Liebesny's⁶⁵ claim for a specific action of a 4 meter wavelength in actinomycosis. Compere⁷⁸ mentioned that short wave diathermy had been claimed to have a specific germicidal action. Haase and Schliephake⁷⁹ observed a more rapid lethal action on staphylococci and tubercle bacilli exposed to ultra short waves as compared with controls heated in water baths to the same temperatures. Hasche and Leung⁸⁰ however exposed cultures of staphylococci and streptococci in distilled water saline solution,

⁶⁷ The writers have recently informed me that the data were taken from a tabulation which appeared in *Grundriss der Kurzwellen therapie* by Holzer and Weissberg. They believe that in the light of present knowledge the data are rather questionable, since it has subsequently been shown (Ostwald and Pajewsky) that measurements made on fresh tissue at body temperature show large deviations from the previously accepted value. Bierman and Schwaizschild believed that heating was more uniform with short wave diathermy than with conventional diathermy and in the recent communication they stated that they did not wish to be classified as selective heating enthusiasts.

bouillon and milk and on agar-plates, to ultra short waves at different frequencies and intensities for periods up to eight and a half hours and they observed no inhibitory or destructive effect on the bacteria. Eidinow²² said that it was untrue that short wave diathermy had any specific action on bacteria. He had made previous studies⁴³ in which sterile gauze, soaked in a broth emulsion of various organisms, was inserted under the skin of normal rats, which were then exposed to ultra short waves of 4.5 and 3.4 meter wavelengths. Eidinow was unable to demonstrate any bactericidal action whatever with these wavelengths, provided the tissues were effectively cooled. He felt that his work confirmed the observations of Christie and Loomis¹³. Mortimer and Osborne⁵⁶ believed that claims for specific bactericidal action of high frequency currents might be more rationally explained on the basis of "point heating" which raised the temperature of the micro-organisms above their thermal death point without a corresponding elevation in the temperature of the medium. They believed that it remained to be proved whether such test tube results could be obtained in the case of infections in the human body.

Ecker and O'Neal⁵¹ attributed the effect on *Bacillus typhosus* agglutinin and complement, in experimental studies on animals exposed to ultra high frequency currents, entirely to the hyperpyrexia which was produced.

Schmidt⁴² observed that there is too great a tendency to look for specific effects, such as on bacteria, for example, the fact being ignored that increased circulation may have a beneficial effect.

It would seem to be the consensus that neither in vitro nor in vivo are there specific bactericidal effects other than those attributable to heat.

PHYSIOLOGIC EFFECTS

It is of course generally accepted that short wave diathermy produces certain physiologic effects which are due to the local or systemic heating which may be produced, but a considerable controversy has arisen as to whether it produces specific effects other than heating.

With regard to the physiologic effects due to heat, Knudson and Schaible⁵ concluded that daily systemic heating of rats to 40.5 C. with short wave diathermy did not retard their growth, appreciably affect their reproductive organs, or produce any pathologic lesions. In another experimental study on dogs, Knudson and Schaible⁵³ found after long elevations of temperature that no physiologic changes were produced other than those attributable to the fever. Bierman¹¹ said that the effect of the application of radiotherapy could be explained on the basis of heat production. Boak and her co-workers⁵⁴ concluded that repeated elevation by short wave diathermy of the bodily temperature of rabbits failed to injure their growth or to interfere with mating, fertilization or the development of young in utero. Hemle and Phelps⁵⁵ reported that exposure to short radio waves produced no effect on the elasticity of aortic rings, and in another study they⁵⁶ concluded that radiotherapy applied to perfused cats' hearts did not modify the natural tendency toward an increasingly hypodynamic state. Eidinow⁴⁴ concluded that the action of ultra short waves was to produce coagulative necrosis and extreme vasodilatation, which was similar to the effect produced by conventional diathermy. There is practically no confirmation of the claims of Weissenberg⁶ that his so called low intensity treat-

ments produce definite physiologic effects,⁵⁸ nor is there any reason to believe that treatments of five minutes or less, as advocated by Stiebock,⁵⁹ have any marked action other than a psychic one.

Schliephake⁹⁰ claimed that, when short wave therapy was used, one was not dealing with heating effects in the ordinary sense, as was still being asserted by some authors, but with a heat which often deviated from that of "thermotherapy and diathermy." No concrete proof of these deviations however, has been forthcoming. Kobak⁹¹ said that, although first interpreted as possessing occult biologic properties characterized as specific in nature, increasing experience has proved that the primary action of short waves was essentially that of heat due to displacement and conduction phenomena. Kobak apparently does not agree with Schliephake's claim that there are "specific effects on colloids," and rightly so since this claim has been fairly well refuted.

The claims of Schliephake, Reiter and a few others regarding specific effects other than heating are as follows:

Schliephake⁹² believed that, in human beings who remained for a long time in the field, there were specific disturbances of the nervous system such as a "desire to sleep," a "high degree of enervation and prostration," "intensive headaches" and "digestive disturbances." He further believed⁹³ that the dividing membranes between the single cells and colloids were "in some way influenced" by short waves and said that this was "a definite effect only produced by the short waves and quite independent of heat." Later he⁹³ contended that there was "point heating in colloidal dispersed substances in the condenser field." Reiter⁹⁴ asserted that a 3.4 meter wavelength had specific destructive effects on Jensen rat sarcoma in vivo. He⁹⁵ claimed also one "obviously specific action" of ultra short waves, namely "an inflammatory effect." Reiter⁹⁶ believed, in addition, that ultra short waves showed a great number of biologic and therapeutic effects which could "not be looked upon as being heat effects alone." Compere⁷⁸ mentioned an "analgesic effect" and a "trophic action." Wilson³⁷ claimed a "peculiar effectiveness" in infections belonging "only to the ultra short waves from 6 to 3 meters." Jellinek⁹⁶ asserted that new-born mice, placed in a weak, short wave field, seemed instantaneously paralyzed, indicating an effect other than heating.

Bauwens⁹⁷ said that short waves primarily made "tissues react against antigens" and secondarily caused local pyrexia. Weissenberg⁶ said that there were "certain specific electrical effects" which had "a sedative influence in a pathological hypertonus of the autonomic nervous system."

Pätzold and Bierman were noncommittal concerning specific effects other than heating. Pätzold⁹⁸ said that the investigations concerning so-called specific effects were too much in flux to necessitate consideration at this early date. Bierman⁹⁷ believed that the question was still "a moot one."

Because of the claims for specific effects the British Empire Cancer Campaign became interested, and Cant, honorary secretary to the scientific committees for this campaign observed: "Effects are claimed in a vast number of diseases. If this be true it would seem that a new and important physical agent is at our disposal." He then announced that the campaign had decided to enable Reiter to continue the investigations which led him to claim to have

obtained "beneficial effects on both carcinoma and sarcoma in animals" Canti further announced that the campaign had instituted a separate investigation by Professor Curtis and Dr Dickens

It is interesting to note that the last named seasoned investigators presented the most definite refutation of the claims of both Reiter and Schliephake After extensive investigations, Curtis, Dickens and Evans⁹⁹ questioned any "specific" actions of short waves which were not primarily thermal in action They said "So far as is known at present from physical and chemical evidence, radiation of these wavelengths (3-15 meters) is not directly convertible into atomic or molecular energy" They traced to their sources the various references of those claiming specific actions and attempted, where possible, to repeat the experiments in question In checking Reiter's⁹⁴ studies, they found that he had taken inadequate precautions against heating, that is, "in order to keep tissue contained in a suitable vessel at 40 C it had to be immersed in a bath containing liquid paraffin at 6 C Under these conditions no effect on metabolism was observed when the specimen was subjected to intense irradiation on a wavelength of 3.4 m" They were unable to confirm the claims of Schliephake and Compere that short waves produced lowering of surface tension in certain colloidal solutions, including blood and serum They found that the stalagmometric method of measurement of surface tension used by Schliephake and Compere was "entirely unsuitable" Using the more accurate and convenient torsion balance method, they were "unable to find any effect whatever on the surface tension of serum, although an effect of the magnitude reported by Schliephake would have been readily detected" They concluded "The variations of surface tension in the short wave field has been referred to in the literature as the 'Schliephake effect' but in our opinion, proof of its existence is entirely lacking"

Furthermore, Curtis and his co-workers refuted the work of Schliephake and Recknagel which claimed changes in the viscosity and stability of colloids other than those caused by a rise of temperature They said that only sixteen lines were devoted to a description of these fundamental phenomena in Schliephake's book and that in reply to their request for fuller information it was learned that this "could not be given 'on personal grounds'" They called attention to the fact that Schliephake failed to mention in his book that Hicks and Szymanowski,⁷⁷ six months after their first paper was published, had withdrawn their earlier results on toxins⁷⁶ (used by Schliephake in corroborating his own work) and had reported that "repeating the work of Schliephake and Haase on staphylococci they were unable to establish any effect of the high frequency field" Curtis and his assistants also tried to duplicate Holzer and Weissenberg's²⁰ "specific actions," notably decolorization of the dye pinacyanol in a short wave field, "but without success," and said that in a personal communication Dr Holzer had stated that he had "since been unable to reproduce the effect" Furthermore they could not verify Esau's observation quoted by Pfomm that turpentine oil could be hardened by exposure to a short wave field, and they could not confirm the "mysterious effects on operators of short wave appliances reported by both Holzer and Schliephake They concluded that if specific effects other than heating exist, "it should be possible for the discoverers to describe at least one clear cut experiment which could be repeated by other workers In

the absence of such evidence we consider that the great mass of inconclusive observations which has been presented is a very insecure foundation for the rapidly growing belief in specific short wave therapy"

Other studies by Dickens and his co-workers¹⁰⁰ caused them to conclude that "the effects on metabolism described by Reiter were really due to heat and not to a 'specific action'" Hill⁷² said that there was no effect from short waves other than heat Hill and Taylor¹⁰¹ studied the behavior of a frog heart, cilia and nerve-muscle preparation exposed to a 3.4 meter wavelength and concluded it was exactly the same as when merely heated in Ringer's solution and that the biologic action of short waves was therefore due to heat Taylor¹⁰² was unable to repeat Reiter's results successfully

Jacobsen and Hosoi¹⁰³ concluded that their own studies and those of Knudson and Schaible¹⁰⁴ revealed the usual picture of hyperthermia and that the effects were not due to any factor other than heat

Wetzel and Kiesselbach¹⁰⁵ studied the effect of 12 and 8 meter wavelengths on tadpoles kept cool by circulating water and observed no differences between treated and control tadpoles

Mortimer and Osborne⁵⁶ decided that the burden of proof still lay on those who claimed any biologic action of short wave currents other than heat Coulter and Osborne¹⁰⁶ came to the conclusion that heat alone was responsible for the therapeutic effects produced by short wave generators, Tenney¹⁰⁷ concluded that general exposures to short radio waves produced simply "a form of fever", Halphen and Auclair⁹ believed the properties attributed to short waves had been explained as being "due solely to the production of heat", Gale¹⁰⁸ said that the effects of short wave therapy must "be assumed to be due to heat effects", Kovacs⁷¹ said that the essential effect of short wave diathermy is heating and nothing else, Wolf⁵⁴ concluded that a specific action did not exist, that short waves exert their influence by the production of heat only and finally the Council on Physical Therapy⁹⁷ concluded that there were no demonstrable specific biologic actions and that, to date, the effects produced could be explained only on the basis of the generation of heat

My own clinical observations have never revealed any of the effects on the nervous system claimed by Schliephake, and exposure of one patient's hand to a 6 meter wavelength for eight hours daily for five days revealed none of the specific inflammatory reactions claimed by Reiter Repeated, long fever treatments by many workers have failed to reveal any such effects Jellinek's¹⁰⁹ claim that his experiment speaks "for the absence of heating" is controversial, since he has not explained his observation on any grounds

The consensus seems quite definitely to be that, in the light of present observations, no specific physiologic effects other than those attributable to heating have been proved Nevertheless the remote possibility of the existence of such effects cannot yet be denied

DISADVANTAGES

The two commonly mentioned disadvantages of short wave diathermy, as compared with other methods of applying heat, are the danger of burns and the difficulty of measuring dosage

Burns—Turrell¹¹⁰ averred that skin burns might occur from short wave therapy, in fact he felt that far more care was required to avoid them than with

conventional diathermy. Wolf¹¹¹ on the other hand, thought burns of the skin less common than with conventional diathermy. Although I¹ previously reported that burns did occur with short wave diathermy and that, in the absence of actual burns, burning sensations were more common than with ordinary diathermy, I nevertheless agree with Wolf that actual burns are less common with short wave than with conventional diathermy. Kling¹¹² said that the assumption that the use of short wave therapy precluded burns and therefore simplified the technique was a dangerous fallacy. He reported six cases of second or third degree burns in which he said¹¹³ healing took place with firm normal scars. Keri-Russell¹¹⁴ had seen "two cases of burns" from short wave diathermy. Speeding² mentioned that occasionally an erythema or even blister formation would take place during short wave treatments. Schliephake³ however, contended that in fifty thousand treatments during the course of six years he had seen burns only twice, and that these were insignificant and healed spontaneously within a few days. Egan¹¹⁵ reported that burns do occur if too strong dosage is used or if perspiration is allowed to remain on the skin, he believed that they were a minor factor in treatment. Kovacs⁷ thought that because less heating effect on the skin occurred than with conventional diathermy there was, generally speaking, less danger of burns in short wave diathermy. The Council on Physical Therapy⁴ reported that burns might occur with any method of applying short wave diathermy.

Another disadvantage which I have previously mentioned¹ is that cords or electrodes may burn, melt or char and that metallic furniture (bed springs particularly) may be unduly heated in the short wave diathermy held and sheets or other coverings may become ignited.

The consensus seems to be that although burns may undoubtedly occur from short wave diathermy, they are less likely to occur than in ordinary diathermy treatments.

Dosage.—With regard to the difficulty in measuring dosage, Kovacs⁷ said that the crude method of measuring it was the greatest present drawback of short wave therapy. Schliephake¹¹⁶ stated that methods of measuring dosage were so complicated that they were useless in medical practice. Although for several years physicians have expressed the hope that an accurate method of measuring dosage might be perfected¹ to date no method of measurement other than through the patient's own sensations has been developed.

ADVANTAGES

Certain advantages are claimed, as follows: more uniform or homogeneous heating than with other thermal methods (Bierman¹¹⁷), more intense local heat which is less hazardous (Davis²²), deeper penetration and greater facility of application (Hollender⁴⁴), the fact that only the middle, more or less straight-lined, part of the field might be used, producing an almost homogeneous heating, the fact that irregularly formed bodily surfaces (open wounds and so on) might be treated with effective doses (Pitzold¹), possibility of introducing air spacing so that only the axial portion of the field was used in therapy (Wilson¹¹⁸), greater efficiency of short wave treatments than of conventional diathermy in heating deeply situated parts in the thorax or abdomen (Cumberbatch¹) and production of a deeper heating

effect, and avoidance of high field concentration around the electrodes with short wave diathermy (Taylor¹¹⁹). I have been particularly impressed with the facility (not the simplicity) of application of short wave diathermy.

The consensus would seem to be that short wave diathermy produces more homogeneous, deeper heating of bodily tissues than other thermal methods, and that there is greater facility of application than with conventional diathermy.

THE USE OF SHORT WAVE DIATHERMY IN THE TREATMENT OF SUPPURATIVE PROCESSES

Out of the hodgepodge of poor presentations, consisting of many small series of uncontrolled cases, one claim has been constantly presented, that is, that short wave diathermy is particularly indicated in the treatment of suppurative processes.

Kobak¹²⁰ recently said that scientifically trained men allowed their first successful laboratory experiments "to overpower their conservative training and critical judgment" and that studies on short wave diathermy "must be presented in that objective and critical manner which recognizes virtues and challenges errors." In no phase of the past studies on short wave diathermy has this "critical judgment" seemed more lacking and "objective" proof less evident than in the observations on its use in the treatment of suppurative processes. So far as can be ascertained not one of the men who so enthusiastically advocated short wave diathermy for suppurative and infectious lesions has presented any systematic, controlled or comparative studies to prove his contentions. No consideration seems to have been given the fact that most superficial suppurative processes (owing to natural bodily mechanisms) go on to prompt regression without any treatment. Mere listing of claims for large numbers of successes without critical proof of these successes is unconvincing.

Schliephake¹¹⁶ has been one of those who while repeatedly having claimed remarkable successes in treating suppurations has presented practically no controlled studies. Thus starting with claims for "extraordinarily quick cure of suppuration" in "about a hundred cases"¹¹⁹ (in 1931), he progressed to the point of claiming (in 1936) to have cured "hundreds of furuncles" in "an average of four and a half days" and large carbuncles in from "ten to fourteen days." He also stated "I have treated forty patients with severe pleural empyema, lung abscesses and suppurative pneumonia with and without gangrene—all of these patients have been cured." He stated that "a furuncle heals occasionally also by hot compresses, but in the short wave field it becomes cured in a much shorter time" (He presented no comparative studies to prove this contention).

Wilson¹¹⁸ also claimed a peculiar effectiveness of short waves in the treatment of infections but presented no comparative studies. Wolf¹¹¹ concluded that short waves have a marked influence on acute and subacute inflammatory processes but he likewise presented no confirming data. Lidinow,⁴ although he found no specific action of short waves on bacteria or tissue cells, suggested that the deeper heating might explain why these waves were of benefit in acute and chronic pyogenic infections. Kobak¹²⁰ formerly expressed the opinion that short wave diathermy had particularly demonstrated its therapeutic value in pyogenic infections. Among those who have reported success in the

trolled studies which led them to believe that short wave diathermy was effective in suppurative lesions may be mentioned Taylor,¹²⁰ Barry¹²¹ and Schmidt.⁴² Kling¹⁰⁴ reviewed the work of twelve authors, and in 695 cases of "infectious conditions" cure or improvement was reported in 80 per cent (Again no controlled studies were reported, and one wonders what percentage would have improved without treatment.)

The most convincing claims concerning the value of short waves in the treatment of suppurative processes came from Egan,¹²² who gave 7,700 treatments to 1,030 patients with pyogenic infections in various bodily areas and concluded that it was of "distinct value in localizing infectious lesions." It has long been known that heat externally applied has these effects and, unfortunately, Egan, despite the excellence of his presentation also has failed to make any definite comparative studies. Egan¹¹⁰ mentioned that "either ultra short wave therapy is not diathermy or else the contraindications to diathermy are ill founded" and that he had been "unable to find the name of the scientist" who said that conventional diathermy was contraindicated in acute inflammatory lesions.

It is probable that this contraindication to conventional diathermy was originally formulated on a purely theoretical basis and that it has been handed down from textbook to textbook without any actual tests to prove the verity of the statement. Kobak⁶⁸ stated that it was "generally known that diathermy of the older type" was contraindicated "in the presence of suppuration." I contend that it has been merely accepted and is not "known." As a matter of fact, physicians have completely ignored this particular alleged contraindication and have treated acute pelvic inflammations with vaginal diathermy with considerable success—making this the single exception to the rule. Cumberbatch⁹⁰ has made a comparative study and has reached the expected conclusion. He wrote "In the endeavor to ascertain whether diathermy is unsafe in the treatment of acute or purulent inflammation I have treated some cases by the short wave method and others by diathermy. Sixty-two cases of carbuncle have been treated. In both forms of treatment there was rapid relief of pain, quick drainage followed and the sloughs separated leaving healthy granulating surfaces. The effects of each form of treatment were indistinguishable and equally quick." Although Cumberbatch's studies would seem to have solved the crux of the entire problem, they will of course need confirmation. Kovacs²¹ pointed out that forms of mild heating other than short wave diathermy "when applied efficiently produce similar resolving and sedative effects."

Hollender⁴⁴ said "We are led to assume from the reports of European workers that surgery is frequently obviated in acute infectious processes but such claims have not been borne out by the experience of workers in this country."

Schliephake's⁹⁰ claim that short wave diathermy was remarkably efficacious in the treatment of pulmonary infections, which he stated had been confirmed by Liebeson,⁶⁰ was not supported by Cumberbatch,⁹⁰ who stated that in one case of empyema with persistent discharging sinus "both diathermic and short wave treatment were unsuccessful." I also attempted to confirm Schliephake's claims and exactly duplicate his technique, as described, using the same type of apparatus and electrodes. Daily treatments for over a month elicited not the slightest change in this particular case.

Further studies are undoubtedly necessary in order to confirm or refute Schliephake's claims. Nevertheless, whereas he stated that all his patients were "cured," at least two failures by other observers can now be noted.

The consensus would seem to be (at the present moment) that short wave diathermy is particularly indicated in the treatment of suppurative lesions, however, insufficient comparative studies have been presented to determine whether short wave diathermy is more effective than other simpler forms of mild heating.

SUMMARY AND CONCLUSIONS

Short wave diathermy has become the accepted term, at least in the United States, for treatment with short radio waves of wavelengths between 3 and 30 meters. Most observers prefer a vacuum tube apparatus of high wattage output for the production of such radiation, although spark gap apparatus has been used effectively by some workers. Devices of low energy output would seem to have no effect other than a psychologic one.

While there appears to be no great difference between the effects produced by conventional and short wave diathermy, short wave diathermy seems to produce deeper, more uniform heating and is more readily applied, although dosage control is more difficult than with conventional diathermy.

So far as competent investigators have been able to determine, there is no demonstrable selective thermal action in the living body. For various physical reasons, short wave diathermy should produce more uniform and deeper heat penetration than conventional diathermy, but for reasons which at present must be purely a matter of conjecture many clinical observations have not confirmed this opinion.

The consensus (particularly of those who have performed careful experiments) would seem to be that the effect of various wavelengths between 3 and 30 meters is approximately the same. There are apparently no specific bactericidal effects other than those attributable to heat either *in vitro* or *in vivo*. There is no reason to believe that treatments of five minutes or less have any marked action other than a psychic one.

In light of present observations, no specific physiologic effects other than those attributable to heating have been proved to exist.

Although burns may occur from short wave diathermy, they are less likely to be found than in conventional diathermy. Lack of a satisfactory method of determining dosage is a definite handicap in administering short wave diathermy.

The chief advantages claimed for short wave diathermy in comparison with other thermal measures are that its action is more homogeneous, there is deeper heating of bodily tissues and it affords greater facility of application. It is claimed that short wave diathermy is particularly indicated in the treatment of suppurative lesions, however, insufficient comparative studies have been presented to determine whether or not it is more effective than other simpler forms of mild heating.

The indications for the use of short wave diathermy should be considered, in light of present knowledge, to be the same as those for the use of conventional diathermy.¹²³ Further studies may prove that other indications do exist.

¹²³ For list of indications see Coulter, J. S. *Medical Diathermy*, J. A. M. A. 106: 209-214 (Jan. 18) 1936.

SATURDAY, APRIL 16, 1938

DR. JAMES H. MEANS ADDRESSES THE COLLEGE OF PHYSICIANS

In his presidential address to the American College of Physicians at its annual session in New York last week, Dr. James H. Means was reported by the *New York Times* to have said:

The behavior of the American Medical Association is political. It is partisan behavior. It champions a cause. At the present time the cause is something close to stand-patism.

Later in his address he said:

We hear a great deal about the sacrosanct doctor-patient relationship. No third party can be allowed to come between the two involved. This has been used as an argument against all attempts to improve the efficiency of medical service through group practice. When it is suggested that a disinterested outside person could with greater equity than the doctor determine what might be a proper fee for services rendered in any given case, there are storms of protest from the conservative wing of the profession. Yet a philosopher might recognize such an arrangement as an ideal one, and, as a matter of fact, it is actually working successfully in more than one place, to the satisfaction of both doctors and patients.

I submit that having a third party determine the size of, and even collect the fee from the patient for the doctor is not only not an intrusion into the holy doctor-patient relationship but actually increases the likelihood of the patient's receiving from the doctor the best and wisest treatment the doctor is capable of giving.

The statement by Dr. Means was heralded by the *New York Times* in headlines on page 1 as a revolt against the American Medical Association. This aroused a storm of protest among the members of the American College of Physicians present at the session. More than 300 members signed a statement, of which the following is a quotation:

Unfortunately a situation has arisen in which the impression has been given in the Public Press that the American College of Physicians is in revolt against the organized medical profession as represented by the American Medical Association.

Inasmuch as no such action has ever been taken by the American College of Physicians and inasmuch as there is reason to believe that the impression created does not correctly reflect the attitude or the membership of the American College of Physicians, we the undersigned fellows of the College respectfully petition the Board of Regents immediately take action to correct this impression publicly.

Dr. Means himself signed this document and issued a personal statement at the banquet on the night following in which he said:

I am not advocating a revolt and nothing of that sort was mentioned in the speech which I made last night.

This statement was duly buried by the *New York Times* on page 11, following a scientific discussion dealing with the history of appendicitis. The Board of Regents of the College of Physicians unanimously adopted the following statement before its adjournment:

Unfortunately an impression has been created that the American College of Physicians is in revolt against the organized medical profession as represented by the American Medical Association. This does not correctly reflect the statement of Dr. James H. Means in his presidential address. Nor does the impression represent my position taken by the membership, since there has been no official consideration by the College of the questions involved.

This statement was duly buried by the *New York Times* on page 19 at the end of a consideration which it headed "Victims of Scumvy Found Among Rich." Altogether the incident may have a salutary effect on the medical profession in establishing with some certainty those to whom it must look for guidance in protecting its established standards and ideals.

DEATHS FROM ENSOL-REX CANCER TREATMENT AND FOOD AND DRUG LEGISLATION

Authorities representing both the Biologic Division of the National Institute of Health and the Food and Drug Administration of the Department of Agriculture are agreed that the deaths in Orlando, Fla., discussed in *THE JOURNAL* last week, were due to Rex, series 152, prepared by the Biochemical Research Foundation of the Franklin Institute of Philadelphia. A portion of this batch, bearing the date of March 7, showed the presence of tetanus toxin, the deaths were due to the preformed toxin developed in the course of manufacture of the product. The two government agencies absolved both the Hendry Connell Research Foundation in Canada and the Franklin Institute of Philadelphia from intentional guilt in the preparation of the serum. Neither Ensol nor Rex had been licensed for interstate sale but were sent broadcast without charge and with a view to obtaining experimental therapeutic evidence. According to statements in Orlando newspapers, an official spokesman for the Food and Drug Administration said:

There is no law to prohibit shipment of dangerous medicines as demonstrated in the famed chloroform case last fall. At that time we recommended that Congress pass laws to cover such situations but to date our recommendations have not been acted upon.

Readers will recall the series of articles in *THE JOURNAL* concerning the Libair of Sulfanilamide Mes-sengill episode in which more than seventy-six persons died following the administration of the chloroform. At that time *THE JOURNAL* said:

A physician is not compelled to follow the United States Pharmacopoeia, the National Formulary or the Council on Pharmacy and Chemistry in the prescription of drugs. He may prescribe anything that he thinks is best for his patient.

for his patient. Indeed, the Council on Pharmacy and Chemistry encourages scientific experimentation with new remedies, provided these experiments are carried out with suitable controls and with adequate facilities for therapeutic investigation. In the usual conditions of practice, however, it is far safer—as this tragedy again emphasizes—to limit prescriptions of nonofficial products to those accepted by the Council on Pharmacy and Chemistry and to use them as described in *New and Non-official Remedies*.

Readers of *THE JOURNAL* will remember that at this very moment people in the United States are being offered other treatments for cancer involving injection into the human body of materials of unknown composition or otherwise uncontrolled and unestablished. The products developed by William Koch in Detroit, by Coffey and Humber in California, and more recently by Beaumont Cornell in Fort Wayne, Ind., are in this category. Perhaps the National Health Institute should concern itself, if possible, under the law, with the use and distribution of these materials. Experiments on animals with the so-called Cornell cure for cancer developed in Fort Wayne resulted in complete failure and the available clinical evidence is hardly worthy the name. As was predicted in discussing the Hendry Connell cancer treatment, the use of such methods will inevitably bring grief to those who are concerned with their employment.

How many additional deaths will be necessary before Congress gives the people of the United States real protection against hastily concocted, secret remedies? How many more human guinea pigs are to be sacrificed by exploiters of unestablished and virtually untested drugs, serums and cosmetics? For five years food and drug bills have been before one or the other branch of Congress. At each hearing, effective provisions for consumer protection in these bills have been deleted in the interest of exploiters. Bill after bill has been emasculated as it came to the Congress for consideration. In their care and concern for the health needs of the people, why do our legislators so persistently evade this issue?

OBITUARIES OF PHYSICIANS PUBLISHED IN 1937

The number of obituaries of physicians published in *THE JOURNAL* during 1937 was 3,398, including 3,277 of the United States, as compared with 3,475 in 1936, also 121 names of Canadian physicians. Three died in China, 2 each in India and Honduras and 1 each in Alaska, British West Indies, the Canal Zone, England, Puerto Rico and South America. The obituaries of 113 women physicians were published, as compared with 103 in 1936. The number of graduates of medical schools in the United States for the fiscal year ended June 30, 1937, was 5,377. Deducting the number of physicians whose obituaries were published, there was a net addition to the profession for the year of 2,100, not including physicians coming from abroad.

Ages—The average age at death of those classified as of the United States was 65.4, as compared with 64.5 in 1936. Twenty-four physicians died between

the ages of 25 and 29, fifty between 30 and 34, 112 between 35 and 39, forty-one between 40 and 44 and four between 45 and 49, two were more than 100. In two cases the age was not reported.

Causes of Death—Heart disease was again the leading cause of death, as it has been for many years. Some contributory causes are included in *THE JOURNAL'S* tabulation, as they have been in former years. For example, when a report of the cause of death gave chronic nephritis and heart disease, it was published as such in *THE JOURNAL* and was recorded on the statistical charts under both diseases. Thus heart disease was reported as a cause of death in 1,360 cases. Endocarditis or myocarditis was specified in 339 cases, coronary thrombosis in 289, angina pectoris in 98 and pericarditis in 2. Other diseases of the heart caused 632 deaths. Pneumonia was the second most frequent cause, with 392 deaths, of which 102 were specified as bronchopneumonia. Arteriosclerosis was the third most frequent cause, with 382 deaths, other diseases of the arteries caused 4. Fourth on the list was cerebral hemorrhage, with 353 deaths, 20 additional deaths were reported as due to paralysis. Of 311 deaths reported as due to cancer, the stomach and liver were reported affected in 59 cases, the intestine in 53, the prostate in 42, the female genital organs in 2 and the skin in 1, in 154 cases the part affected was not specified. Nephritis was reported as the cause of 172 deaths. The number of cases in which hypertension was reported was 91, embolism and thrombosis exclusive of coronary thrombosis 83, diabetes mellitus 73, uremia 63, other diseases of the genito-urinary system 74, diseases of the prostate other than cancer 58, tuberculosis 56, influenza 43, cirrhosis of the liver 35, senility 31, septicemia 21, appendicitis and ulcer of the stomach and duodenum 19 each, other diseases of the digestive system 15, intestinal obstruction 17, peritonitis 16, leukemia 15, bronchitis, meningitis and brain tumor 14 each, other tumors 10, paralysis agitans and diseases of the liver 13 each, aneurysm, biliary calculi and cholecystitis 7 each, arthritis, asthma, hernia and Hodgkin's disease 6 each, cellulitis, encephalitis, erysipelas and pernicious anemia 5 each, cerebral sclerosis, otitis media, pulmonary infarct and streptococcal infection 4 each, Addison's disease, carbuncle, empyema, hyperthyroidism, malaria, multiple sclerosis, phlebitis, sinusitis, streptococcal sore throat and *Streptococcus viridans* infections 3 each, agranulocytic angina, amebic dysentery, intestinal diverticulitis, Ludwig's angina, ileus, pellagra, scarlet fever and thromboangitis obliterans 2 each. Other diseases reported as causing one death each were acromegaly, aplastic anemia, bacillary dysentery, brain abscess, dementia paralytica, diphtheria, diverticulum of the esophagus, ectopic pregnancy, encephalomalacia, hemochromatosis, hiccup, intestinal rupture, Kummel's disease, lipid dystrophy, mediastinitis, multiple myeloma, myasthenia gravis, osteoarthritis, osteitis deformans,

parotitis, periarteritis nodosa, poliomyelitis, polyneuritis, progressive muscular atrophy, staphylococcal infection, substernal goiter, syringomyelia, thrombocytopenic purpura, typhoid fever, typhus, pyloric ulcer and undulant fever

Accidental Deaths—One hundred and fifty-one physicians died as the result of accidents in 1937, compared with 182 in the previous year. Automobile accidents accounted for 71 deaths, falls 37, drowning 5, shooting, airplane accidents, carbon monoxide poisoning from automobiles and overdoses of medicine 4 each, x-ray burns and electricity 2 each, burns, explosion, gas, poison and street car accident 1 each. In twelve cases unexplained fractures were given as causes of death. One physician died of injuries and exposure after his car stalled in a snowstorm while en route to attend a patient, one of strangulation by a lamp cord.

Suicides and Homicides—Suicide was the cause of 52 deaths published in 1937. Bullet wounds accounted for 25 of these deaths, poison 10, hanging 5, incised wounds 4, gas and overdoses of morphine 2 each, chloroform and jumping 1 each. In two cases the method was not reported, in addition twelve deaths from the following causes could not be classified because of insufficient information: overdose of morphine 4, barbitol poisoning 3, cyanide poisoning, carbon monoxide poisoning, illuminating gas, shooting and strychnine poisoning 1 each. There were 12 homicides.

Civil Positions—Among the decedents were 219 physicians who were or had been teachers in medical schools, 434 who had served in the World War, 17 veterans of the Civil War and 51 veterans of the Spanish-American War. One hundred and seventy-one were or had been health officers, 124 members of boards of education, 81 members of boards of health and 15 members of state boards of medical examiners. There were 52 who were or had been coroners, 38 members of state legislatures, 36 mayors, 32 pharmacists, 31 bank presidents, 24 members of city councils, 21 authors, 20 editors, 13 missionaries, 9 dentists, 8 police surgeons, 7 clergymen, 5 postmasters, 5 lawyers, 3 judges, 2 congressmen, 2 governors, 1 lieutenant governor and 1 justice of the peace. There were 13 members of the U. S. Army Medical Corps, 9 of the U. S. Navy Medical Corps, 16 of the U. S. Public Health Service, 4 of the Veterans' Administration and 7 of the Indian Medical Service.

Association Officers—Among those who died who were or had been officers of the American Medical Association were Dr. George H. Simmons, Editor and General Manager Emeritus, 2 vice presidents, ten section officers and 3 members of councils. Thirty-one members or former members of the House of Delegates died during the year. There were also 29 presidents or former presidents of state medical associations, 2 presidents-elect and 5 secretaries.

Current Comment

"LIBERTY" AND MEDICINE

For some weeks *Liberty*, published by Macfadden Publications, has been printing what purports to be an expose of medical practice by one Dr. "George B. Raymond." The story is called "Doctors Don't Tell." An editorial note intimates that this is a true story and that its purpose is to expose evils that are hidden by medical ethics. From all over the country have come protests from both nonmedical readers and physicians against the obvious lack of dependability in this material. If the statements are honest and susceptible of verification, the author should not hesitate to attach his name. Evidence now available indicates however, that the prefix "Dr." before the author's name should also have been in quotation marks. A telegram was sent to Macfadden Publications asking the editor to confirm the fact that the articles had been prepared by an individual who had failed to receive a medical degree and who had admitted deceit in the securing of a license. Apparently Macfadden Publications does not wish to answer this question. These statements indicate how little creditability can be given to or dependability placed on this alleged expose of medical ethics in *Liberty*.

NATIONAL CANCER SURVEY

The United States Public Health Service announced¹ in September 1937 the appointment of a National Advisory Council to the National Cancer Institute. This council consists of six scientists, of whom three are doctors of medicine. At that time the erection of the cancer institute on a site in Bethesda, Md., was announced.² The institute is to be part of the National Institute of Health. By provisions of a House joint resolution of the Seventy-Fifth Congress, third session, the President of the United States proclaimed April of each year as "Cancer Control Month" and invited governors of the several states, territories and possessions to issue like proclamations.³ The Woman's Field Army of the American Society for the Control of Cancer immediately became interested. As a result, cancer is the subject of much publicity during this month. The Minnesota house of representatives has urged that the Postmaster General permit a cancer slogan "Early Cancer is Curable" to be used on postal meters which are used by large organizations in lieu of affixed postal stamps.⁴ In Maryland, cancer activities are sponsored by the cancer committee of the Medical and Chirurgical Faculty—the state medical society. In Passaic County, N. J.,⁵ the county medical society has taken the leadership and so also has the medical society in Allegheny.

5 Cancer Control Month Monthly Bull. Maryland State Department of Health April 1938 p. 9.
6 Passaic County's Cancer Week Bull. Am. Soc. Control of Cancer February 1938 p. 8.

County (Pittsburgh)⁷ The United States Public Health Service, meantime, is conducting a survey by questionnaire, asking physicians to report information about cancer patients for whom they have cared during 1937. This information can be reported so that its reporting will not violate the confidential character of physician-patient relationships. Since cancer is not a reportable disease, cooperation from physicians in this survey will be purely voluntary. It may entail considerable labor and some inconvenience, but it is desirable and in the public interest. The first step toward conquest of any disease is a complete knowledge of its prevalence.

PLAGUE TRANSMISSION

In the thirty years since the Indian Plague Commission demonstrated that fleas act as the transmitting agents of bubonic plague, the flea has been the only insect considered of importance in the natural dissemination of this disease. Observations of the course of several outbreaks have demonstrated¹ that the intensity of epidemics of plague is regulated not by the total number of fleas on the rats of the communities but rather by the species of fleas with which the rats are infested. In fact, as far as is known, plague epidemics have never occurred in communities where *Nosopsyllus fasciatus* has existed alone to the exclusion of *Xenopsylla cheopis*. Experimental investigations indicate that the latter flea is much more susceptible to plague infection than any of the other fleas tested. Sixty-six per cent of *cheopis* fleas fed on infected guinea pigs were found to harbor the plague bacillus in comparison with only 21 per cent of all the other fleas similarly exposed. The *cheopis* fleas when successfully infected had an average length of life of only sixteen days, and only one reached a maximum of thirty-six days. From the information now available regarding plague-infected fleas, it is possible to explain tentatively the reasons why plague outbreaks in different parts of the world have varied so much in character. In the warm localities where *cheopis* constitutes the only rat flea found, plague epizootics have frequently subsided quickly in accordance with expectation based on the experimental observation that plague-infected *cheopis* fleas do not survive long and therefore do not remain infective for long periods. As the bites of these fleas may readily transmit plague, however, the human incidence of infection will usually be high where this variety is abundant. In the colder climates, where the *fasciatus* is present in a relatively high proportion, plague outbreaks may be prolonged but are generally associated with relatively few human cases. In conclusion, Eskey² points out that those fleas which are most susceptible to plague infection of the gastrointestinal tract and to the bacterial obstruction of the esophagus are the most dangerous vectors. As long as the flow of blood to the stomach is not blocked, infected fleas may bite on their hosts without danger of transmitting the disease, although some danger of infection exists from the virulent organisms present in the feces of all infected fleas.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

State Medical Meeting at Tucson—The forty-seventh annual meeting of the Arizona State Medical Association will be held in Tucson April 21-23 with headquarters at the Santa Rita Hotel and under the presidency of Dr. Harold W. Rice, Bisbee. Guest speakers who will address the scientific sessions are:

Dr. Franklin G. Ebaugh, Denver, Frequent Psychiatric Complications in General Practice
Dr. John H. Woolsey, Woodland Calif., Regional Ileitis
Dr. Albert S. Crawford, Detroit, Craniocerebral Injuries
Dr. Jay C. Davis, Minneapolis, Effect of Drugs on Coronary Circulation
Dr. Leslie M. Smith, El Paso, Texas, Lesions of the Oral Cavity
Dr. Stuart W. Harrington, Rochester, Minn., Diaphragmatic Hernia

Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will address a public meeting at the University of Arizona auditorium Thursday evening on "Medicine and the Changing Social Order." He will also address the house of delegates at an open meeting Friday afternoon on "Medicine and the National Policy," and the Woman's Auxiliary Thursday afternoon. The other guest speakers will speak at round table luncheons Thursday and Friday, and there will be clinics Friday and Saturday mornings at the Pima County, Comstock, Southern Methodist and St. Mary's hospitals, the Southern Pacific Sanatorium, the Desert Sanitarium and the U. S. Veterans' Facility. The annual banquet and dance will be Friday evening at the Santa Rita. Saturday afternoon a golf tournament and a fishing trip to Guaymas have been arranged.

CALIFORNIA

Lectures for the Public—Stanford University School of Medicine, San Francisco, opened its popular medical lectures" April 1 with a talk by Dr. Walter W. Boardman on "Conditions of the Mouth in Relation to Disease." Others in the series include:

Dr. Donald E. King, April 22, Backache, Causes and Treatments
Dr. William J. Kerr, May 6, Forty Fat and Florid and Heading for Circulatory Failure
Dr. Dwight L. Wilbur, May 27, Vitamin Facts and Fallacies

Changes Among Health Officers—Dr. Alphonso O. Skancky has been appointed health officer of San Bruno to succeed the late Dr. Frank Holmes Smith. Dr. Martha E. D. Rinehart-Allen is the new health officer of Fairfax, succeeding Dr. Bernard J. Conroy. The city of Indio has transferred its public health administration to the Riverside County Health Department. The city of Santa Cruz has transferred its administration of public health affairs to the Santa Cruz County Health Department.

Another Death from Rabies—A laborer in Los Angeles died in the Los Angeles General Hospital March 12 from rabies, according to the *Weekly Bulletin* of the state department of health. He had been bitten on the finger about February 22 by a dog which he saw lying in the street, apparently dead. When he attempted to pick up the dog it bit him and ran away. No attention was paid to the bite until after the onset of the illness. The patient died within twenty-four hours after entering the hospital.

FLORIDA

Medical History of St. Augustine—A survey of the medical history of St. Augustine is being made in conjunction with a survey of the history of the locality as a part of a plan to restore the city as the first permanent settlement in the United States, according to the *Journal of the Florida Medical Association*. The project is sponsored by the National Committee for the Preservation and Restoration of Historic St. Augustine, the chairman of which is John C. Merriam, president of the Carnegie Institution of Washington. It is being carried out in cooperation with the institution. A committee from the St. Johns County Medical Society is collaborating with the research unit in collecting and arranging data for the survey of the medical history. Members are Drs. Jacob John Spencer, chairman, Vernon A. Lockwood and Robert D. Harris, Jr. Search is being made for data on the Indian concept of medicine at the time Menendez founded St.

Augustine, the effects on the health of the Indians of contact with the colonists, the medical methods and facilities of the colonists during the first Spanish occupation, the English occupation, the second Spanish occupation and the period which followed the purchase by the United States. The sites of early hospitals have been located and it seems that the first hospital built within the limits of what is now the United States was the hospital of Santa Barbara. This hospital was built by De Canzo, Spanish colonial governor of Florida, in about 1600. It is expected that one of these early hospitals will be included in the buildings selected for restoration, and it is planned to establish a medical museum in the restored hospital. Physicians interested are asked to communicate with Dr Spencer, 32 Saragossa Street, St Augustine.

GEORGIA

State Medical Meeting at Augusta, April 26-29—The Medical Association of Georgia will hold its annual meeting at the Forest Hills Hotel, Augusta, April 26-29, under the presidency of Dr George A Traylor, Augusta. The Abner Wellborn Calhoun Lecture will be delivered Wednesday by Dr George H Semken, New York, on "The Problem of the Lump in the Breast." Dr Irvin Abell, Louisville, Ky, President-Elect, American Medical Association, will also give an address Wednesday. The Richmond County Medical Society will be host and the speakers will include

Dr Richard Frank Slaughter Jr Augusta Relief of Causalgic like Pain in the Isolated Extremity by Sympathectomy
Dr Trumble C Johnson Atlanta Diagnostic Traps in Gastroenterology
Dr Cornelius F Holton Savannah Use of Atabrine in Treatment and Control of Malaria Among a Group of Industrial and Agricultural Employees in Georgia
Drs Henry C Frech Jr and Perry P Volpitta both of Augusta Amnesia in Labor Comparing Pentobarbital and Hyoscine with Seconal and Hyoscine
Dr Benjamin T Bersley Atlanta, Altered Mechanics of the Female Peritoneal Supports
Dr Robert M Harbin Jr Rome Clinical Observations of the Use of Sulfanilamide
Dr Stacy C Howell Atlanta Would You Recognize a Case of Glaucoma?

A symposium on pneumonia will be held Wednesday afternoon, the speakers to be Drs Joseph Dewey Gray and Morris C Fulton, Augusta, Thomas L Ross, Macon, Stewart R Roberts, Atlanta, and Charles H Richardson, Macon. Entertainment will include the annual dinner of the alumni of Emory and Georgia university schools of medicine, golf and the annual banquet Thursday evening, when Dr Eugene E Murphey, Augusta, will be toastmaster. The woman's auxiliary will meet in Augusta April 26-29.

ILLINOIS

Society News—Dr Karl D Dietrich, Columbia, Mo, addressed the Adams County Medical Society, Quincy, March 14, on "Relation of Urology to Obscure Abdominal Symptoms."—At a joint meeting of the Sangamon County Medical Society and the Springfield Medical Association in Springfield, March 3, Dr Bernard Iantus and Ralph Terry, Ph.D., Chicago, discussed "Progress in Therapeutics."—Dr Walter C Alvarez, Rochester, Minn, addressed the Springfield Medical Club, Springfield, March 17, on "Disorders of the Gastrointestinal Tract."

Chicago

Dr Harris' Library Given to County Hospital—The medical library of the late Dr Malcolm L Harris, President of the American Medical Association 1928-1929, has been given to the library of Cook County Hospital by Mrs Harris. The collection consists of about 600 volumes. Dr Harris served his internship at the hospital and later was attending surgeon.

Society News—At a meeting of the Chicago Society of Internal Medicine March 28 Dr Sidney A Portis among others spoke on "Chronic Bacillary Dysentery."—The Chicago Medical Society was addressed March 16 by Drs Herman L Kretschmer on "Importance and Significance of Pyuria in Children" and John L Reichert, "Vaginitis in Childhood."

INDIANA

Military Training for Reserve Officers—A course in medical military instruction will be given to all medical reserve officers in the fifth corps area and to members of the Indiana State Medical Association May 23-27, in accordance with a request made by army officers newspapers report. The course will be held in connection with the annual graduate meeting in Indianapolis sponsored by the state medical association and the Indiana University School of Medicine. The fifth corps area includes Indiana, Ohio, Kentucky and West Virginia.

KANSAS

Appointment of County Health Officers—The following county health officers have recently been appointed

Dr Edwin R Hill Jr Lyons Rice County
Dr August A Meyer Alma Wabaunsee County
Dr Orlin P Wood Marysville Marshall County
Dr Alfred J Horejsi Ellsworth Ellsworth County
Dr Benjamin Brunner Wamego Pottawatomie County
Dr Raymond W Moore Eureka, Greenwood County
Dr Frank A Trump Ottawa Franklin County
Dr Franklin R Croson Clay Center Clay County
Dr Benjamin L Phillips Paola Miami County
Dr Leon W Zimmerman, Liberal Seward County
Dr Ivan B Parker Hill City Graham County

The following physicians have been reappointed as county health officers: Spencer B Dykes, Esbon, Jewell County; Robert J Lanning, Junction City, Geary County, and Donald A Bitzer, Washington, Washington County.

Society News—The Labette County Medical Society was addressed February 23 in Parsons by Drs Winfred L Post Joplin, Mo, on "Foreign Bodies in the Air Passage and Therapy of the Lung Through the Bronchoscope" and Hugh D McGaughey, Joplin, "X-Ray Radiation in Nonmalignant Conditions."—The Saline County Medical Society was addressed in Salina in February by Drs Donald A Anderson and Ernest E Harvey, Salina, on "Treatment of Syphilis and 'Clinical Use of Protamine Zinc Insulin'."—Dr Edgar A Pickens Wichita, addressed the Ford County Medical Society in Dodge City February 11 on "Management of Prostatic Obstruction."—At a joint meeting of the Shawnee County medical and dental societies in Topeka, March 17, the speakers, all of Topeka, were Louis Fleisch, D.D.S., on "Interrelation of Preventive Medicine and Preventive Dentistry," Dr James G Stewart, "Relationship Between Focal Infection and General Medicine," C N Mertz, D.D.S., "Oral Infections in Relation to Systemic Infection," and Harold W Powers, "Relationship Between Sinus Disease and the Teeth."

MARYLAND

Annual Session of Medical and Surgical Faculty—The annual meeting of the Medical and Surgical Faculty of Maryland will be held at the Beldere Hotel, Baltimore, April 27. The program will be made up of round table discussions in which the following, among others, will participate

Dr James G Arnold Jr The Value of Sulfanilamide in the Treatment of Various Types of Meningitis
Dr Harold R Bohlman, Use of Sulfanilamide in Orthopedics
Dr Lloyd G Lewis Carcinoma of the Prostate
Dr Arthur M Shipley Acute and Chronic Pericarditis
Dr James Dawson Reeder Fistula in Ano Diagnosis and Treatment
Dr William Raymond McKenzie Fractures Involving the Paranasal Sinuses
Dr Edgar B Friedenwald The Common Cold in Children
Dr Walter E Dandy Lesions of the Cranial Nerves
Dr Thomas S Cullen Uterine Hemorrhage and Its Cause

MISSISSIPPI

State Medical Meeting at Jackson—The seventy first annual session of the Mississippi State Medical Association will be held at the Robert E Lee Hotel, Jackson, April 19-21, under the presidency of Dr William L Little, Wesson. Guest speakers will include

Dr Troy P Bagwell Knoxville Tenn Management of Anterior Polymyositis
Dr Newdigate M Owensby Atlanta Ga The More Recent Concepts and the Management of Mental Maladies
Dr Edwin Gurney Clark Nashville New and Standard Practices in the Management of Syphilis
Dr Raphael E Semmes Memphis Tye Ear Nose and Throat Evidence of Intracranial Disease
Dr Ralph O Rycheimer Memphis Lacrimal Apparatus
Dr Francis C LeJeune New Orleans Hoarseness
Dr Philip W Brown Rochester Minn Certain Deficiency Disorders in Intestinal Disease
Dr Leon J Menville New Orleans Carcinoma of the Cervix
Dr Maxwell E Lapham New Orleans Management of Breech Presentation
Dr Isidore Cohn New Orleans The Making of a Surgeon

Dr James S McLester Birmingham Ala Past President of the American Medical Association will deliver the Fawcett Howard Oration on Causes and Effects of Hypertension. The Mississippi State Pediatric Society will meet Monday April 18 with the following speakers: Drs Stanley Gib on Chicago Management of Pneumonia in Childhood; M Hines Roberts Atlanta Ga An Evaluation of Our Method of Protection Against Certain of the Infectious Diseases; Felix J Underwood Jackson The Immunization Problem in Mississippi; and Horton R Casparis Nashville The Endocrines as Related to Children. Dr Gibson will also address the annual banquet on "The Diagnosis of Heart Disease in Childhood." The Mississippi State Hospital Association will meet April 18.

MONTANA

Graduate Lectures—Graduate meetings will be held in Miles City, April 25-26, Livingston, April 27-28, and Missoula, April 30 May 1, under the auspices of the Medical Association of Montana. The speakers will be Drs Myrie G Peterman, director, department of pediatrics, Marquette University School of Medicine, Milwaukee, Morris Edward Davis, associate professor of obstetrics and gynecology, University of Chicago School of Medicine, and Francis W Lynch, St Paul. Dr Davis will speak on "The Prophylaxis and Treatment of Puerperal Infection." Medical Complications of Pregnancy, and 'Common Obstetric Operations.' A public meeting will be held at Missoula, April 30, on syphilis.

NEBRASKA

State Medical Meeting at Lincoln—The annual assembly of the Nebraska State Medical Association will be held in Lincoln April 26-28 at the Hotel Cornhusker. The meeting will open with a symposium on syphilis at which Dr Charles C Dennie, Kansas City, Mo., will be the guest speaker. Another symposium will be on pediatric subjects with Dr Philip C Jeans, Iowa City, as the guest speaker. Other guests will be

Dr Clayton J Lundy Chicago Early Diagnosis and Prevention of Rheumatic Heart Disease
Dr Karl A Meyer Chicago Cancer of the Stomach
Dr John Zahorsky St Louis The Clinical Aspect of Poliomyelitis
Dr Lawrence P Engel Kansas City Mo. title to be announced
Dr August A Werner St Louis Female Sex Hormones
Dr Geza de Takats Chicago Diagnosis and Management of Peripheral Vascular Disease
Dr Vilray P Blair St Louis title to be announced

Drs Werner, Engel and Meyer will also speak at a luncheon meeting Wednesday and Drs Blair and de Takats Thursday. Dr Dennie will address a dinner meeting Tuesday on "The Effect of Malaria on Syphilis and Other Diseases in South America," and Dr Lundy will show a motion picture on "Interpretation of a Normal Electrocardiogram." Dr Homer Davis, Genoa, is president of the association.

NEVADA

Annual Registration Due May 1—All persons holding licenses to practice medicine in Nevada are required by law to pay annually to the treasurer of the Board of Medical Examiners on or before May 1 a tax of \$2. Failure to do so operates to forfeit a licensee's right to practice medicine, and his license to practice can be reinstated thereafter only on the payment of a \$10 penalty.

NEW YORK

Buffalo Alumni Meeting—The fourth annual "Spring Clinical Day" sponsored by the Alumni Association of the University of Buffalo School of Medicine will be presented April 23 at the Hotel Statler, Buffalo. The guest lecturers will be Drs Albert A Berg, Russell L Cecil and Robert A Cooke New York, William Boyd, Toronto, Ont., Donald Guthrie, Svre Pa., Walter I Lillie, Philadelphia, and William P Murphy, Boston. Dr Francis D Leopold Buffalo, is president of the alumni association, is general chairman for the event.

Health Commissioner Honored—Dr Henry Burton Doust, health commissioner of Syracuse, was guest of honor at a luncheon given by the Onondaga Health Association and a dinner given by the Onondaga County Medical Society April 5, celebrating his thirty years of service to the city. Dr Doust established the tuberculosis bureau in the department of health in 1908 and remained as its head until his appointment as health officer last January. He is professor of clinical medicine at the Syracuse University School of Medicine and has served as president of the Onondaga County Medical Society and the Syracuse Academy of Medicine.

Society News—The New York State Association of Public Health Laboratories will hold its twenty-second annual meeting May 23 at the Mary Imogene Bassett Hospital, Coopers-town. Dr Raphael Schullinger, Brooklyn, addressed the Buffalo Radiological Society and the Buffalo Otolaryngological Society February 14 on "Roentgenologic Aspects of Mastoiditis." Dr Douglas Quick, New York, will address the Syracuse Academy of Medicine April 19, on "Present Trends in the Treatment of Cancer." Dr Abraham H Aaron Buffalo addressed the quarterly meeting of the Ontario County Medical Society Genoa April 12 on Medical Treatment of Gastrointestinal Patients in Whom Surgery Has Failed. The Obstetric Society of Syracuse Hospitals was recently formed with Dr Ferdinand I Schoeneck as president and Dr Glenn A Wood as secretary.

New York City

Professor Appointed—Dr Joseph F McCarthy, professor of clinical urology, New York Post-Graduate Medical School, has been appointed professor of urology and attending urologist to the New York Polyclinic Medical School and Hospital. Dr McCarthy graduated from Columbia University College of Physicians and Surgeons in 1901.

The Adam Miller Lecture—The second Adam M Miller Memorial Lecture was delivered at the Long Island College of Medicine March 23 by Dr George L Streeter, Baltimore, of the department of embryology, Carnegie Institution of Washington on "Recent Advances in Knowledge of Early Stages of Development in Primates." The lectureship was established in memory of the late Adam M Miller, M A, dean and professor of anatomy at the college.

Medical College Dinner—The annual dinner of the New York Medical College and Flower Hospital and the Fifth Avenue and New York Ophthalmic hospitals was held March 18 at the Waldorf Astoria. The speakers were Drs Arvid Lundau, professor of pathology and bacteriology, University of Lund, Sweden, on "Pathogenesis of Gastric Ulcer" and For-dice Barker St John on "Surgical Treatment of Gastric Ulcer, with Report of 800 Cases Over a Twenty Year Period."

Society News—A program of papers on syphilis was presented before the Medical Society of the County of New York March 28 by Drs Thomas Parran, surgeon general, U S Public Health Service, Washington, D C., David J Kaliski, George Miller MacKee and Howard Fox. Dr Norman E Titus addressed the New York Physical Therapy Society March 2, on "Electrotherapy in Fibromyositis", Jerome Weiss and Hans J A Behrend, "Advances in the Treatment of Foot Disabilities with Special Reference to Prophylaxis"—Drs Condit W Cutler Jr and Carl Eggers addressed the New York Surgical Society March 9 on "Conservative Surgery for Peptic Ulcer."

Cancer Exhibit for the World's Fair—Plans for an exhibit sponsored by the New York City Committee of the American Society for the Control of Cancer at the New York World's Fair 1939 were recently announced. The exhibit will consist of models and dioramas primarily designed to show the weapons that can be used in fighting cancer. Dioramas showing the Curies at work, Roentgen in his laboratory, historical scenes in the development of surgery, models of high voltage x-ray tubes, and models showing the mining of radium will be included. A motion picture showing the progress of experimental work on cancer and a figure of a woman etched on glass and lighted from the back to show how the disease spreads are other features. The members of the committee to select the subject matter for the exhibit are Drs Francis Carter Wood, John C A Gerster, Ira I Kaplan New York, Mandel H Weinstein, Long Island City, Bowman C Crowell, Chicago, Stanley P Reimann, Philadelphia, Miss Katherine Tavis, Mrs Robert G Mead and Mrs Francis J Rigney.

OHIO

Postgraduate Day in Youngstown—The annual Postgraduate Day sponsored by the Mahoning County Medical Society will be held April 28 at the Hotel Ohio Youngstown. The speakers will be Drs Frank H Lahey, Gilbert Horrax, Everett D Kiefer and Elmer C Bartels, all of Boston.

Society News—Dr Isidor S Raydm, Philadelphia, addressed the Summit County Medical Society, Akron March 1, on "Surgical Problems of the Biliary Tract." Dr Morris Edward Davis Chicago, addressed the Mahoning County Medical Society, Youngstown, March 15, on "Treatment of Hemorrhage Occurring Late in Pregnancy." Drs Joseph H Barach, Pittsburgh, and Thomas E Newell, Dayton, addressed the Stark County Medical Society, Canton at its annual meeting February 9 on "The Present Status of Medicine in South American Countries." Dr William G Lennox, Boston, addressed the Academy of Medicine of Cincinnati March 15 on "Migraine and Epilepsy—Newer Concept and Treatment." Dr Alfred Blalock Nashville Tenn. addressed the academy March 8 on "Hypotension and Hypertension." Dr Stanley E Dorst, Cincinnati addressed the Toledo Academy of Medicine March 4, on "The Role of Vaccine Therapy in Bacterial Sensitivity."

PENNSYLVANIA

Society News—Drs David L Farley and Walter Estell Lee Philadelphia, were the guest speakers at the annual spring clinic of the Locoming County Medical Society at the Williamsport Hospital April 8. In the morning both officiated at clinics and in the afternoon Dr Farley presented a paper on "Recent Advances in the Field of Hematology" and Dr Lee

on "Tumors of the Intestinal Tract"—Dr Herbert Lund, Uniontown, addressed the Fayette County Medical Society, Uniontown, April 7, on 'Medicolegal Aspects of Recent Court Trials'—Dr Louis W Wright, Harrisburg, addressed the Dauphin County Medical Society, Harrisburg, March 1, on "Problems, Diagnosis and Treatment of Syphilis"

Seminars for Practitioners—The Schuylkill County Medical Society will sponsor six graduate seminars at the Pottsville Hospital beginning April 21 and continuing on succeeding Thursdays. The following program is announced:

Dr Jesse O Arnold Philadelphia Common Obstetric Problems
Dr Edward J G Beardsley Philadelphia Clinical Diagnosis
Dr Elliott P Joslin Boston Diabetes
Dr Ralph M Tyson Philadelphia Pediatric Diseases
Dr Hugo Roesler Philadelphia Heart Disease and Electrocardiography
Dr Morris Fishbein Chicago Editor of THE JOURNAL, Modern Obstetrics versus Old Fashioned Maternity Care

Philadelphia

Postgraduate Institute—The third annual Postgraduate Institute of the Philadelphia County Medical Society was held March 28 to April 1 at the Bellevue-Stratford Hotel with a registration of 1,705. The general subject was 'Diseases of the Digestive Tract,' discussed in eighty-seven lectures by Philadelphia physicians and in scientific and technical exhibits. Dr Arthur C Christie, Washington D C, delivered the annual J Chalmers DaCosta Foundation Lecture, Wednesday evening March 30 on 'Comprehensive Planning for Medical Care—the Physician's Responsibility.' At this meeting Dr Frederick J Bishop, Scranton, president of the Medical Society of the State of Pennsylvania, and George H Meeker, Ph D, dean of the University of Pennsylvania Graduate School of Medicine, also made addresses. Dr Rufus S Reeves was chairman of the committee that organized the institute.

Pittsburgh

Joint Obstetric and Gynecologic Meeting—The Obstetrical and Gynecological Society of Allegheny County had a joint meeting with the obstetric and gynecologic section of the Academy of Medicine of Cleveland April 4. Clinics were held at the Allegheny General and Magee hospitals and in the evening papers were presented by Drs James S Taylor, Altoona, on 'The Incidence of Cesarean Section in Allegheny County', Arthur J Skeel, Cleveland, 'Reducing Maternal Mortality in Cleveland,' and Robert L Faulkner, Cleveland, 'Gynecological Mortality Rate at the Cleveland University Hospitals.'

VIRGINIA

Society News—Drs Lawther J Whitehead, Richmond and Wright Clarkson, Petersburg, addressed the Mid-Tidewater Medical Society, West Point, recently, on 'Treatment of Acute Infections with X-Ray' and 'Cancer and Its Treatment by Radium and X-Ray' respectively. Dr Hawes Campbell, Enfield, discussed 'Distribution of Public Welfare Funds in the Counties and Cities of Virginia'—Dr Henry B Mulholland, Charlottesville, addressed the Nansemond County Medical Society, Suffolk, recently, on new advances in therapy.

WASHINGTON

Society News—Dr Frank R Menne, Portland Ore, was the guest speaker at the annual meeting of the Tacoma Surgical Club April 2, the program was devoted to discussions of cancer—Drs Albert W Holman and Herbert V Thatcher, Portland, addressed the Cowlitz County Medical Society, Longview, February 9, on 'Extra-Uterine Pregnancy' and 'Surgery of the Hand' respectively—Drs Clyde R Jensen and Kyran R E Hynes, Seattle, addressed the Grays Harbor County Medical Society, Aberdeen in February on 'Arteriosclerosis, Hypertension and Diet' and 'The Clinical Approach to Jaundice' respectively—Drs George D Capacito, Seattle, and Edwin E Osgood, Portland addressed the Pierce County Medical Society, Tacoma, January 25 on edema and anemia respectively—At a meeting of the Yakima Valley Medical Society, Yakima, February 14 the speakers were Drs Albert C Stewart and Carroll C Carlson, Tacoma on 'Hospitalization for the Neurotic Patient and The Present Status of Medical Treatment of the Psychoses' respectively—Drs Joseph W Shaw and Stephen T Parker addressed the King County Medical Society, Seattle, March 21, on 'Treatment of Early Syphilis' and 'General Principles in Treatment of Syphilis' respectively—Dr Emile F Holman, San Francisco, guest speaker at the annual meeting of the Seattle Surgical Society, February 4-5 spoke on 'Peripheral Vascular Disease: Diagnosis and Treatment and Indications for and Technique of Splenectomy.'

GENERAL

Child Health Day—May-Day—Child Health Day sponsored by the Children's Bureau at the request of the State and Provincial Health Authorities of North America will be observed Sunday May 1 with supplementary observances April 30 and May 2. This year's slogan will be 'Speed children on the road to health.' State health officers are to appoint state chairmen to arrange for activities of public and private organizations.

Remington Medal Award—The Remington Medal of the New York branch of the American Pharmaceutical Association will be awarded to Henry C Christensen, Pharm M, Chicago, secretary of the National Association of Boards of Pharmacy, it is announced. Mr Christensen was appointed to his position with the national association in 1914. He has been a councilor of the American Pharmaceutical Association since 1925 and was president in 1930.

International Cancer Congress in 1939—Dr Francis Carter Wood, New York, is president and Dr Donald S Child, Syracuse N Y, is secretary treasurer of the third International Cancer Congress to be held in Atlantic City Sept 11-16 1939 with headquarters at Haddon Hall. Dr Alfred L Loomis Bell, Brooklyn, is in charge of transportation and exhibits. Sections proposed for the congress are general research, biophysics, genetics, general pathology, surgery, radiologic diagnosis, radiotherapy statistics and education. The membership fee will be \$15. Inquiries should be addressed to the Institute of Cancer Research, 1145 Amsterdam Avenue, New York, N Y.

Survey of Radium Supply—About 82 Gm of radium is owned by 213 hospitals surveyed in forty-seven cities in the East and Middle West, according to preliminary reports of a survey being conducted by the Eldorado Radium Corporation, which owns the Eldorado mines on Great Bear Lake in Canada discovered seven years ago. At the present price of \$25,000 a gram, this amount is valued at about \$2,050,000. The largest single holder is Bellevue Hospital, New York with 95 Gm, second is Memorial Hospital, New York with 89 Gm. Others with a large supply include State Institute for the Study of Malignant Diseases, Buffalo, 825 Gm and Michael Reese Hospital, Chicago, 65 Gm.

Otorhinolaryngologists to Meet—The forty-fourth annual meeting of the American Laryngological, Rhinological and Otological Society will be held in Atlantic City April 27-29. Two symposiums are announced, one on laryngeal cancer and one on allergy. In the first the speakers will be Drs Henri Coutard, Paris and Chicago, Paul Klemperer, William Harris and Charles J Imperatori, New York, Henry B Orton, Newark, N J and LeRoy A Schall, Boston. On allergy the speakers will be Drs Maximilian A Ramirez and Varian F Jones, New York, French K Hinsel, St Louis and Harris P Mosher, Boston. One session will be devoted to consideration of 'Chemoprophylaxis as a Means of Preventing Poliomyelitis.' Dr Rea E Ashley, San Francisco will give an address and Dr Austin A Hayden, Chicago will present a motion picture on the practical application of the technique. Other addresses will be:

Dr Victor E Negus, London, 'Evolution of the Speech Organs of Man.'
Dr David R Higbee, San Diego, 'Further Observations on the Autonomic Nervous System.'
Dr Henry L Williams, Jr, Rochester, Minn, 'The Underlying Factors Concerned in Otic Hydrocephalus.'
Dr John A Kolmer, Philadelphia, 'Sulfanilamide in the Treatment of Experimental Streptococcus and Pneumococcus Meningitis.'
Dr Samuel J Crowe, Baltimore, 'Diagnosis and Differential Diagnosis of Deafness.'
Dr Max A Goldstein, St Louis, 'Thyroxine Therapy in Otosclerosis.'
Dr Horace J Williams, Philadelphia, 'Otitis Media and Orbital Cellulitis in Scarlet Fever and a Preliminary Report on the Loss of Hearing in This Disease.'

Dr Samuel J Kopetzky, New York, is president of the association and Dr Harold I Lillie, Rochester, Minn, is president elect.

Government Services

Congress of Military Medicine

Major General Charles R Reynolds, surgeon general, U S Army, has been designated by President Roosevelt as president of the permanent committee of the International Congress on Military Medicine and Pharmacology which will meet in Washington D C in May 1939. At that meeting, General Reynolds will become chairman of the organizing committee and president of the congress. This is the first meeting of this congress organized at the close of the World War in the Western Hemisphere.

Foreign Letters

LONDON

March 19, 1938

The Law Relating to Abortion

An important debate on the law relating to abortion, in which both the medical and the legal profession took part, was arranged by the Fellowship of Medicine. Sir Beckwith Whitehouse, gynecologist, proposed the motion "That the law of abortion requires reform." He described the law as harsh in its implications as regards the potential mother. Pregnancy could be legally terminated only when the mother's or the child's life was threatened. The law had not the slightest interest in the mother, apart from dissolution. Both the medical and the legal profession were endeavoring to find loopholes in the law for making an obvious wrong a right. We no longer subscribed to the doctrine that the life of the child was paramount and that so long as the mother's life was preserved it did not matter what physical or mental wreck she became. Abortions, including so-called therapeutic abortions, were increasing. It was with regard to abortions undertaken for bona fide medical reasons that he asked for reform of the law. As the law stood, they were illegal. As suggested in Taylor's "Jurisprudence," the law should be reenacted by inserting the proviso "to exempt from liability the fully qualified practitioner who terminated pregnancy for the bona fide purpose of preserving the mother from special danger to life or health." But two clauses should be introduced to tighten up certain weaknesses in the preceding clause. Illegal though it was, so-called therapeutic abortion was being performed today by well known members of the medical profession for indications which were not accepted by others. He was skeptical about the sympathetic attitude with which the problem was sometimes approached. If the law should be reformed to include the health of the mother as an indication, the number of such cases would increase. Two weapons were available against the unscrupulous patient and the "sympathetic" practitioner: (1) notification of all cases of therapeutic abortion before the operation is performed, (2) the unanimous agreement and consent of a board of three individuals—the family physician, the surgeon who performs the operation, and a disinterested physician, surgeon, obstetrician or alienist with a special knowledge of the condition for which the operation is suggested. Notification would act as a deterrent to the potentially criminal type of applicant. Notification should be to one of the health authorities, preferably the county authority or the Ministry of Health, to avoid local publicity of domestic details. The reform would tighten up the existing law and limit the activities of medical abortionists. No hardship would be imposed on the genuine patient, and the division of responsibility would be welcomed by the bona fide practitioner. If "reform" simply implied increased license to perform an operation which the majority of obstetric surgeons detested, Sir Beckwith Whitehouse would be no party to it.

Opposition to the motion was led by Dr W. H. F. Oxley, who said that agitation for reform came from three groups: (1) those who wished to enlarge the scope of abortion so as to include all cases in which a woman wished to have her pregnancy terminated whatever the reason; (2) those who aimed at reduction of illegal abortions by increased stringency of the law; (3) physicians anxious to have a clear statutory definition of the indications which would make artificial termination of pregnancy lawful. Only the two latter groups need be considered as the thesis of the first was immoral. There was no proof that abortion was increasing in this country; the deaths due to it had remained steady. While he agreed with the object of the second group, he believed that their methods would be ineffective. Illegal abortion was clandestine and therefore the

cases in which information was desired would be the ones in which it was not forthcoming. The vast majority of abortions were brought about by simple means by respectable married women for economic reasons, and physicians were not called in at all. The physician should perform abortion only for preserving the life or health of his patient and not for sociologic or eugenic reasons. He did not believe there ever was a prosecution of a physician who kept within his province.

Dr Letitia Fairfield thought that the practical interpretation of the law as regards the health of the mother was so broad that it did away with the necessity for the very limited reform advocated. The medical board of three meant formalism, delay, obstruction and interference in clinical matters. Mr. Kitchen, lawyer, would like to see the law declare that it is lawful for a physician to induce abortion if he believes in good faith that the pregnancy would be injurious to health. He would also include the rare cases in which pregnancy follows rape or incest. On a show of hands there was a majority, but not a large one, in favor of the motion.

Increase in Number of Medical Students

The following figures have been published:

Medical Students in the British Isles

| | Men | Women | Total |
|---------------------|--------|-------|--------|
| 1928 | 7 279 | 1 108 | 8 387 |
| 1935 | 11 176 | 1 747 | 12 923 |
| Percentage increase | +53.5 | +57.7 | +54.2 |

Guy's Hospital Gazette considers that these figures give cause for alarm. A few years ago there was in England one physician to every 800 of population, a figure which was considered to indicate that the saturation point had been reached. During the period of seven years from 1928 to 1935, while the population has not increased by 4 per cent, the number entering the medical profession has increased by more than 50 per cent. Such a relative increase of physicians to the population must mean that the public will pay more for medical care or that physicians will earn less or, more probably, both. It is not an inviting prospect for the medical student, whose training yearly becomes more exacting.

PARIS

(From Our Regular Correspondent)

March 19, 1938

Curie Hospital May Close for Lack of Funds

The Hospital and Radium Institute of the Curie Foundation may be forced to close unless a large subsidy is given by the city of Paris. During the past year there has been a sharp decline in the revenues of the foundation, whose work is known all over the world. The chief sources of revenue in the past have been donations and government subsidies, in both of which a constantly increasing diminution has been noted. The increase in the cost of maintenance of the hospital and the institute has made it necessary to consider their closing unless a relatively substantial subsidy can be secured from the city of Paris. A strong effort is being made by leading members of the city council to grant such a subsidy.

Erythema Nodosum and Pulmonary Tuberculosis

Two recent papers again call attention to the association of erythema nodosum and pulmonary tuberculosis. Dr Etienne Bernard and his associates at the January 7 meeting of the Societe medicale des hopitaux stated that erythema nodosum appears to have a definite place in cases of pulmonary tuberculosis. It has been most commonly reported as being observed at the period of primary infection, i.e., the period of hyperallergy. Their patient was a woman aged 39, who presented the clinical picture of a relatively benign pleuropulmonary tuber-

culosis a year before. About ten months later a recurrence of the pleurisy was noted, accompanied by erythema nodosum. The latter did not appear at the time of the primary infection, thus differing from cases reported by other French phthisiologists.

At the January 14 meeting Dr M J Comby told of a man aged 26 whose father had pulmonary tuberculosis. At the age of 4 years the patient had an acute serofibrinous pleurisy from which he had apparently recovered. The erythema nodosum did not appear until seventeen years later, so it was necessary to be careful in stating that an erythema nodosum appeared only during a primary tuberculous infection. Dr P G Jacob stated that erythema nodosum could be present at any stage of a pleuropulmonary tuberculosis. These cases were not as rare as commonly believed. Dr Jean Troisier said that in 95 per cent of the cases the erythema nodosum is the sign of a recent primary infection. It is often seen at the time when a negative tuberculin skin test becomes positive. He believed that in Dr Comby's case the attack of pleurisy at the age of 4 years had been a primary tuberculous infection and the second attack at the age of 26 years a reinfection. Dr Halle was of the opinion that more and more evidence was being compiled to show the tuberculous nature of erythema nodosum. In some cases studied by Debre, Saenz and others the bacilli had been found in cultures taken from the lesions. The lesions appear almost symmetrically on the arms and legs near the elbow and knee, never elsewhere. They are accompanied by gastrointestinal symptoms and do not show any tendency to break down, as does a lupus vulgaris. In other types of tuberculous skin lesions observed in children, there is an absence of such a symmetrical distribution.

Physicians Set Example in Raising Large Families

In the March 6 issue of the *Concours medical* an editorial by Dr J Noir states that the decrease in the number of births in France is becoming serious. The number of deaths constantly exceeds the number of births. Of ten million families, there are less than three children in more than seven million families. A praiseworthy effort is being made by the government to raise the birth rate by granting allowances which increase in proportion to the number of children in each family. These allowances, or allocations as they are termed here, are conscientiously distributed among the laboring class, but sparingly in the agricultural and moderate income groups. The medical profession in France has not waited to receive government aid to encourage the raising of large families but has formed an independent organization which already includes sixty-one medical families of more than ten children each. The majority of the fathers are physicians in country districts or small towns. One physician is listed as having seventeen, another sixteen and a third fifteen children.

Rockefeller Foundation Endows Chair of Neurosurgery

About \$50,000 has just been granted to the Medical School of the University of Paris to establish a chair in neurosurgery. The first to occupy this position will be Dr Clovis Vincent, whose contributions to this special field are widely known. Unable to secure beds in the public hospitals of Paris, Dr Vincent organized his own hospital where more than 600 brain operations were performed in 1937. With the cooperation of the public hospital authorities he will now have wards at his disposal for neurosurgical work. Opportunity for research in this field will be greatly aided by the Rockefeller Foundation Endowment.

New Public Health Decoration

The minister of public health Mr Rucart has established a new form of reward for those who render meritorious service in public health. The new order will have three grades or ranks: chevaliers or knights, officers and commanders. The official ribbon worn by those on whom this honor is bestowed will be blue.

Death of Prof Félix Mesnil, Parasitologist

Another of the original group of co-workers of Louis Pasteur has passed away at the age of 70 years. He became associated with the Pasteur Institute in 1892 and made a special study of parasitology. One of his earlier contributions was a book on trypanosomes and trypanosomiasis written in collaboration with Professor Laveran. He was one of the first to introduce chemotherapy in the treatment of tropical diseases and organized the teaching of tropical medicine at the Pasteur Institute of Paris. His pupils are scattered all over the globe. For thirty-five years he occupied the position of editor of the Bulletin of the Pasteur Institute.

VIENNA

(From Our Regular Correspondent)

March 10, 1938

Epidemic of Psittacosis in Vienna

Vienna was recently much disturbed to learn that several members of one of the city's best known and most distinguished theatrical families, who had been suffering from an obscure illness, had been admitted to the hospital with symptoms suggestive of psittacosis. Public interest increased when subsequently it became known that the attending physician and the consultant internist, Professor Hitzengerger, had shown the same symptoms and were hospitalized. That the disease was psittacosis had been declared by Professor Hitzengerger himself, who apparently had become infected on his first visit to the ailing actors. While waiting for the identification of the causative agent of psittacosis, which bacteriologic work is done at the Veterinary Research Institute in Moedling, the number of persons affected by the epidemic had risen to twelve, now including not only members of the theatrical family and the two doctors but the servants and two callers on the family. There was one fatality. The sources of infection were found to have been a zebra-parakeet purchased six weeks before and a canary that had been a household pet for many years. Observations made at the Veterinary Research Institute in Moedling, of which Professor Dr Gerlach is director, show that the filtrable virus of psittacosis often may be present as a latent infection in apparently healthy birds, which act as 'bacillus carriers'. Transmission can take place by means of contaminated bird seed and the sneezing of sick birds or the disease may be communicated as a 'dust disease'. As psittacosis is highly contagious the laboratory and hospital workers have to be protected by special measures such as the wearing of masks and rubber gloves. The health authorities issued a warning over the radio to all owners of zebra parakeets and other cage birds to exercise the utmost caution in handling them. In Vienna, especially during the last few years, a vast number of small psittacaceous birds have been bred and marketed the keeping of these creatures having assumed the proportions of a veritable fad. Following the outbreak of this epidemic, however, many perturbed people turned their pets over to the animal shelters. The course of the disease in the eleven surviving patients was somewhat as follows: high continued fever with temporary remissions, multiple lobular foci in the lungs, great prostration. In short, the clinical picture of a lingering influenza in which the true state of affairs is disclosed by laboratory tests. In small epidemics previously observed the mortality lay between 10 and 20 per cent.

Axillary and Rectal Temperatures in Acute Abdominal Disorders

During the past fifteen years Professor Dr Demmer has been concerned with the fact that often in the course of various diseases noteworthy differences are evidenced between simultaneously recorded temperatures in the axilla and in the rectum. Dr Demmer recently reported the results of his studies before the Gesellschaft der Aerzte in Vienna. He studied the records of simultaneous axillary and rectal temperatures in 200 cases.

of acute inflammatory abdominal disorders. In each case the normal divergence of 0.5 degree C was greatly exceeded, the variations ranging from a minimal 0.7 degree to 1.7 degrees. Dr. Demmer considers this abnormal circumstance an indication for operation regardless of the absolute temperature levels. His judgment has been virtually always corroborated by the condition revealed at operation. The author ascribes particular importance to a constant abnormal difference in temperature between axilla and rectum as evidence that peritonitis threatens, even if other classic symptoms are absent. Of the 2,050 cases, 1,400 represented acute appendicitis and operations were performed in 35 per cent of these rather late in the course of the disease, in some cases too late to save life. In 217 (14 per cent) of the 1,400 cases of appendicitis only imperfect classic symptoms had developed, in eighty-four cases (6 per cent) such symptoms were lacking. Conversely, abnormal difference between axillary and rectal temperature was absent, on the basis of positive clinical and surgical observation, in only eleven cases (8 per thousand). The difference was manifested in only twenty-one cases (1.5 per cent) with no inflammation of the organ. According to the foregoing determinations, the classic symptomatology was marked in 14 per cent. On the contrary the axillary rectal temperature symptom was defective in only 8 per cent in which the pathologic conditions were disclosed at operation and in 15 per cent of the operations which revealed no abdominal inflammation. Thus in the vast majority of cases the temperature difference provides almost sure criteria with regard to the presence of a pathologic abdominal process (peritoneal irritation) necessitating surgical intervention. Greater importance should be attached to a difference that has increased within the space of a few hours than to a constant difference although the latter is also extremely pathognomonic. Since in elderly persons cutaneous temperature is as a rule only slowly adjusted to an increased temperature of the internal organs, the sign is especially likely to be manifested in older patients. The sign affords a means of differentiating extraperitoneal inflammatory processes from intraperitoneal conditions which threaten life and which urgently require treatment. The abnormal difference in temperatures provides a timely indication for surgical treatment of a threatening peritonitis and thus saves precious time that otherwise might be lost in a fruitless establishment of organic diagnosis. If one properly interprets this sign, obscure abdominal disturbances can be quickly recognized as inflammatory or noninflammatory. In the discussion, many of those present, including some of the internists, corroborated the soundness of the guiding principles outlined. Many internists have observed that among elderly patients pneumonia, migraine and coronary thrombosis may all run a course without elevation of axillary temperature although simultaneously the rectal temperature may show clear elevations. Increased difference in temperature is, however, most important for surgical considerations and should be evaluated as a warning signal.

Knowledge of Hydrocephalus

The neurologist Professor Marburg recently read a paper in the *Gesellschaft der Aerzte* on the problem of hydrocephalus, in which he stated that the term 'hydrocephalus' denotes a pathologic increase in the amount of cerebral fluid and a concomitant dilatation of the cerebral ventricles. As etiologic factors traumas, syphilis and inflammations are to be considered besides other processes which signify only an increased permeability of the vessels and the hematoencephalic barrier without manifestation of inflammation. Clinically hydrocephalus is differentiated as fetal (balloon head), early infantile (mostly caused by trauma at parturition), late infantile, juvenile or adult. Significant syndromes are hydrocephalus epilepticus, intracranial pressure syndrome, hemiplegia syndrome, Nonne's syndrome and disintegrative syndrome. These conditions are now best distinguished by means of roentgenography and above all by

ventriculography and encephalography. By the use of a contrast medium the diagnosis has been made so much easier that resorption tests have come to be dispensed with. Hydrocephalus is a problem of permeability of the vessels. This accounts for the excess flow of cerebral fluid into the ventricles, which causes the latter to become dilated. The condition becomes regulated and stabilized by means of the metabolism, the production of hormones and the nervous system. The therapeutic approach must be through these channels. The most favorable results have been achieved by roentgen therapy; other measures are merely symptomatic and palliative. In the discussion, pediatricians and roentgenologists present stressed the value of roentgen irradiation in hydrocephalus but also pointed out that frequently serous meningitis or slowly developing cerebral tumors and cerebral tubercles can present a clinical picture similar to that of hydrocephalus. Statistics collected by the neurosurgeon Schoenbauer were cited. Of 1,372 brain operations in his service, only thirteen were undertaken solely to relieve hydrocephalus. In only one of these thirteen cases was uncomplicated primary hydrocephalus proved by intervention and necropsy. In four other cases on the basis of some other diagnosis it was decided to operate and primary hydrocephalus was found. In 60 per cent of all cases of space-infringing cerebral processes (tumors, inflammations and so on) hydrocephalus will be present. If such patients are first treated with roentgen rays their condition usually deteriorates and they come to operation in bad condition. Accordingly Schoenbauer recommends the establishment of the diagnosis of "simple hydrocephalus" before any irradiation has been tried.

Radon in Treatment of Pleural and Peritoneal Exudation

Dr. Laszlo recently reported to the *Gesellschaft der Aerzte* on radon insufflation of the thoracic and abdominal cavities in cases of carcinomatous pleurisy and peritonitis. This procedure, followed by the speaker since 1935, tends to inhibit formation of exudate and to reduce the required number of punctures to a minimum. Laszlo insufflated 300 cc of oxygen through a fluid containing 500,000 miche units of emanation. He treated a patient with carcinomatous pleurisy following mastectomy, whose condition had required frequent puncture, with an "emanation pneumothorax." Small quantities of insufflated gas sufficed to induce the desired remission of the exudative process. Dr. Laszlo used the same therapy repeatedly in similar cases as well as in ascites. Whereas formerly, in cases of carcinomatous effusion, puncture was necessary every two or three days, the emanation therapy checked the production of effusion so effectively that intervals of from two to three weeks and even longer were permissible.

ITALY

(From Our Regular Correspondent)

Feb 15, 1938

International Congress of Pediatricians

The fourth International Congress of Pediatricians, held at Rome, was attended by 900 practitioners from all parts of the world, thirty-eight countries were represented. The executive committee was headed by Professor Spolverini, director of the *Clinica di Roma*. In his address of welcome he reminded his hearers that ancient Rome in imperial times was the source of much precautionary legislation with regard to problems of demography, of the nursing and of the child. Among the promulgators of such measures were Julius Caesar, Augustus and Trajan. The speaker also mentioned the fact that the first foundling hospitals were instituted in medieval Rome. He then went on to describe the principal social agencies and legal provisions which safeguard the infant and the younger generation in the Rome of today.

The first theme for discussion was social and clinical aspects of the neuropsychoses encountered in pediatric practice.

Speakers were Jundell of Sweden, Glanzmann of Switzerland, Allen of the United States and others. After an expansive development and discussion the following resolution was adopted:

1 Psychoneuroses of childhood and the concomitant problems of child training form an important part of pediatrics

2 These disorders should be a concern of the ward and out-patient services of every pediatric clinic

3 Courses in pediatrics ought to give adequate consideration to the therapy of these conditions, and to their prophylaxis through proper training

4 It is of paramount importance that doctors, especially pediatricians and school medical officers, should act as instructors of the public and should advise parents with regard to various problems of child guidance and training

5 The authorities ought to provide the medical profession the necessary support in these activities, the practitioner should be afforded the opportunity to improve his training by direct educational contact with the populace

On the motion of Professor Pechere it was recommended that all secondary schools and especially girls' high schools should offer instruction in child psychology

The second theme for discussion was the relation of mineral metabolism and water exchange in early childhood to the problem of artificial feeding. Papers were read by McQuarrie of the United States and Csapo of Hungary. McQuarrie first reviewed the diverse composition and dynamic function of the bodily water content, both the intracellular fluid (70 per cent of the total) and the extracellular fluid (the latter is subdivided in its turn into intravascular and interstitial fluids). He then discussed the physiologic and clinical importance of the semipermeable membranes interposed between the two systems. On these membranes depends the maintenance of approximately uniform osmotic concentration values in the body fluids. These fluids and the blood plasma bear a striking resemblance to the secretions of the gastroenteric tract, at least with respect to the ionic structure, however great may be the differences in chemical composition. These data have been practically applied with notable success to the problems of vomiting and diarrhea of infants as well as to the effects of electrolytic and acid base equilibrium.

In the second paper Csapo provided detailed illustrations of the interrelation of water and salt exchange, which are in close correlation in the healthy nursing but which follow diverse paths if the baby is ill. This is especially perceptible in acute nutritional disorders. Of the various factors that regulate water exchange the author believes that those pertaining to the kidneys are the most important, the capability of dissolution is not always perfect.

The third topic on the agenda was childhood tuberculosis. The discussion was divided into three subheadings: (1) recent studies of ultravirus, (2) contagiousness of tuberculosis in infants and (3) prophylaxis and therapeutics. Part 1 was dealt with by Professors Dufourt of France and Cohen of Belgium, assisted by Aguirre of Argentina and Fiore of Italy. The conclusions formulated by the speakers occasioned a lively debate between the convinced adherents of the ultravirus theory (Fiore, Frontali, Dufourt) versus the opponents of the theory. Cohen remained uncertain. The most impressive arguments were advanced by Professor Petragham, director general of public health for all Italy. He scouted the alleged existence of ultravirus and especially the possibility of experimental demonstration of an ultravirus of tuberculosis by means of our present equipment.

The problems of prophylaxis and therapeutics were sources of further controversy. Papers on these themes were submitted by Noeggerath of Germany and Chester Stewart of the United States. The congress was in accord with respect to the fundamental need for various social regulations and facilities for isolation but there was some difference of opinion with regard to the relative feasibility of various prophylactic measures.

Questions were raised as to the practicability of vaccination and whether it should be carried on with live bacilli (which procedure is not entirely free from danger) or with dead bacilli (the efficacy of which is challenged by many authors). The Italian school insisted on the efficacy of prophylactic inoculation with dead germs and Professor Petragham announced that new experiments were being conducted on the applicability of an inhalation antitoxin, his own concept.

It was decided to hold the next International Congress of Pediatricians in the United States.

Mediterranean Fever

At a medical meeting in Faenza, Dr. Guido Drei talked on Mediterranean or undulant fever as it is encountered in that region of Italy known as Romagna. The author cited various discussions and publications to establish that this disease was unknown in Romagna till some twenty years ago. Subsequently, at intervals, cases have been reported within the region but the diffusion has been remarkable. The contagion is imported principally by herds of sheep which are penned up for the winter in the neighborhood of tenant farm houses. The numerous springtime abortions occurring among these animals are of the infectious type that tends to become epizootic. As a result of their proximity and contact with the sheepfolds, cattle also may become infected, the farmer first becomes aware that something is amiss when the cows begin to drop stillborn premature calves. On the basis of his epizootic and epidemiologic studies in Romagna, Drei concludes that there are two types of causative agent. The first, *Bacillus abortus* Bang, causes epizootic abortion but is rarely pathogenic in man; the second, the micrococcus of Bruce, is abortifacient in sheep and cattle and through these intermediate hosts, pathogenic in man as well. As to the mechanism of transmission, from the animal to man, the sum of data indicate that direct contact with an infected beast is usually responsible for isolated cases and that the pathogenic organism follows the alimentary tract.

In the course of the same meeting Professor Guigni emphasized the increased clinical incidence of the disorder, describing how the early enlargement of the liver often exceeded that of the spleen and is a specific sign in differential diagnosis. Treatment with specific vaccine intravenously administered appears the most effective means of abbreviating or (quite frequently) abruptly checking the long febrile course. The author surmises that the apparent failure of serotherapy in some cases and the slight reactions to the serum in others have a basis in the species of the intermediate host—cases in which cattle were inculcated reacted more intensely and more effectively to the serum than cases traceable to contact with sheep. Guigni's observations were confirmed by Professor Fontana, whose personal observations have led him to conclude that sheep rather than cattle are more likely to transmit undulant fever directly to man.

Marriages

RICHARD J. S. SILVIS, A. Surg., Lieut. (j. g.) U. S. Navy, to Miss Naomi Holt, both of Great Lakes, Ill., Dec. 7, 1937.

ANDREW BURNET WHITAKER to Miss Phebe Greenleaf Knight, both of Camden, S. C., in December 1937.

WINSTON TUCKER LA NEAVE JR. to Miss Nellie Rawls of Franklin, Dec. 31, 1937.

JOHN P. SCHEBLE, Milwaukee, to Miss Teresa McCormick of Madison, Wis., Nov. 27, 1937.

EARL M. SLAGHT, Elsie Mich. to Miss Carol May Durpan of Sebawaing, in December 1937.

HARVEY E. HOLTZ, Iowa City to Miss Arlene Breck of Traer, Iowa, February 12.

JOHN C. TILLEY to Miss Katherine Matthews, both of Memphis, Tenn., January 7.

Deaths

Louis Burgin McBrayer ☉ Southern Pines, N C, Louisville (Ky) Medical College 1889, for twenty-one years secretary and treasurer of the Medical Society of the State of North Carolina and at one time president, formerly secretary of the Hoke County Medical Society and past president of the Buncombe County Medical Society, coroner of Buncombe County, 1901-1907, health officer of Asheville, 1909-1914, president of the Southern Conference on Tuberculosis, 1925-1926, at one time member and president of the state board of medical examiners, managing director of the North Carolina Tuberculosis Association, 1915-1937, fellow of the American College of Physicians, formerly superintendent of the North Carolina State Sanatorium for the Treatment of Tuberculosis, Sanatorium, and was active in organizing the fight against tuberculosis in the state, was chairman of the board of directors of the North Carolina Odd Fellows Orphanage of which he had been a member for several years, aged 68, died, April 1

Norman Jerome Blackwood ☉ Medical Director, Rear Admiral, U S Navy, retired Santa Barbara, Calif, Jefferson Medical College of Philadelphia, 1888 entered the navy in 1890 and retired in 1930 on or after attaining statutory retirement age, fellow of the American College of Surgeons, superintendent of the Santa Barbara Cottage Hospital, at one time medical director of the Provident Hospital, Chicago, aged 72, died, April 1

George Franklin Jackson ☉ Little Rock, Ark, Eclectic Medical University, Kansas City, Mo, 1911, member of the Radiological Society of North America, medical director of the Pyramid Life Insurance Company, on the staffs of the Arkansas Children's Home and Hospital, St Vincent's Infirmary, Baptist State Hospital and the Missouri Pacific Hospital, aged 49, died, January 25, in a local hospital, of heart disease

John Franklin Culp ☉ Harrisburg, Pa, University of Pennsylvania Department of Medicine, Philadelphia, 1886 member of the American Laryngological, Rhinological and Otolaryngological Society, fellow of the American College of Surgeons past president of the Dauphin County Medical Society, aged 72, for many years on the staff of the Harrisburg Hospital, where he died, January 17, of adenocarcinomatosis

Leonidas Mosby Anderson ☉ Lake City, Fla, Atlanta Medical College, 1895, past president of the Florida State Medical Association and the Columbia County Medical Society, formerly member of the state board of medical examiners, was recently appointed inspector of the state institutions and administration advisor by the state board of health, aged 76, died, January 21, of carcinoma

Walter Fred Wiese ☉ Fresno, Calif, University of Illinois College of Medicine, Chicago, 1915, fellow of the American College of Surgeons, member of the city board of education, on the staffs of the Burnett Sanitarium St Agnes Hospital and the General Hospital of Fresno County, aged 49, died, January 29, at the University of California Hospital, San Francisco, of heart disease

Edward Hill Baldwin, Newark, N J, New York Homeopathic Medical College and Hospital, New York, 1895, formerly member of the state board of medical examiners of New Jersey, fellow of the American College of Surgeons, consulting surgeon to the Homeopathic Hospital of Essex County East Orange and St Mary's Hospital, Passaic, aged 66, died, January 30, of coronary thrombosis

William Schuyler Colfax, Pompton Lakes, N J, College of Physicians and Surgeons, Medical Department of Columbia College, New York 1887, formerly mayor of the borough president of the board of education, member and president of the board of health and health officer of the community, aged 72, died, January 17, of coronary thrombosis

Edward Pease Swift, Rye, N Y, Hahnemann Medical College of Philadelphia 1881 emeritus professor of medicine, New York Homeopathic Medical College and Flower Hospital, New York, at one time on the staff of the Metropolitan Hospital, New York, aged 79, died January 15, of carcinoma of the prostate with metastases to the lungs

Edward Cargill Ehlers, Essex Fells, N J, University and Bellevue Hospital Medical College, New York 1899, served during the World War police marshal and formerly health officer of Essex Fells, aged 67, died January 17 in the Mountside Hospital, Glen Ridge, of chronic myocarditis and arteriosclerosis

Wharton Greene Leak, East Bend, N C, North Carolina Medical College, Davidson, 1900, member of the Medical Society of the State of North Carolina, aged 63, died, January 19, of diabetes mellitus and streptococcal cellulitis of the arm, following an accidental wound from a hypodermic needle lying on his desk

Ivy Stansell ☉ San Antonio, Texas, Southern Methodist University Medical Department, Dallas, 1914, served during the World War, police surgeon, formerly member of the staff of the Robert B Green Hospital, aged 49, died, January 9, in a local hospital, of gastric ulcer, myocarditis and pleurisy

George Streitt, New Haven Conn, Yale University School of Medicine, New Haven, 1901, member of the Connecticut State Medical Society, at one time on the staff of the Connecticut State Hospital, Middletown, formerly health officer of Torrington, aged 60, died, January 5, of heart disease

John Campsey Knox, Washington, Pa, Ohio State University College of Medicine, Columbus, 1908, fellow of the American College of Surgeons, served during the World War, for many years on the staff of the Washington Hospital, aged 59, died, January 15, of cerebral hemorrhage

Milton Ellis Lando ☉ Oakland, Calif, Cooper Medical College, San Francisco, 1900, veteran of the Spanish-American War, for many years on the staff of the Children's Hospital of the East Bay, aged 57, died suddenly, January 31, of arteriosclerosis and cerebral hemorrhage

Isham Faison Hicks, Dunn, N C, North Carolina Medical College, Davidson 1902, member of the Medical Society of the State of North Carolina, formerly secretary of the Hartnett County Medical Society, aged 61, died, January 21, of chronic myocarditis and phlebitis

Arthur D Houghton ☉ San Fernando, Calif, Hahnemann Medical College and Hospital, Chicago, 1902, formerly member of the city council of Los Angeles, served during the World War, aged 66, died, January 23, in the Good Samaritan Hospital, Los Angeles, of carcinoma

John Joseph Brownson ☉ Dubuque Iowa, State University of Iowa College of Medicine, Iowa City, 1886, member of the board of education for many years county physician, formerly on the staff of the Mercy Hospital, aged 81, died, January 29, of myocarditis

Abraham Herman Barr ☉ Linden N J, New York Homeopathic Medical College and Flower Hospital New York, 1911, on the staffs of the Alexian Brothers' Hospital and St Elizabeth Hospital, Elizabeth, aged 51, died, January 1, of coronary thrombosis

Grant A Neal, Alabama, N Y, University of Buffalo School of Medicine, 1893, for many years health officer of the town of Alabama and at one time county coroner, aged 69, died, January 7, in the Batavia (N Y) Hospital, of lobar pneumonia

Robert Rodgers, Atlantic City, N J, University of Pennsylvania Department of Medicine, Philadelphia, 1889 at one time member of the city council and board of education of Philadelphia, aged 74, died, January 4, of chronic myocarditis and nephritis

Isaac David Wood, Slacauga Ala, University of the South Medical Department, Sewanee, Tenn, 1901, member of the Medical Association of the State of Alabama, on the staff of the Slacauga Hospital, aged 63, died, January 30, of pneumonia

James Roy Beaver ☉ West Pittston, Pa, Medical College of Philadelphia 1911, at one time medical director of the public schools, aged 49, on the staff of the Pittston Hospital, where he died, January 16, of ruptured duodenal ulcer

Noah Bunyan Adams, Murphree, N C, Tennessee Medical College Knoxville, 1896 member of the Medical Society of the State of North Carolina served during the World War, aged 69, died, January 20, of arteriosclerosis and hypertension

Myron Scott King ☉ Boulder, Colo, College of Medical Evangelists Los Angeles 1925, aged 47 on the staff of the Boulder-Colorado Sanitarium and Hospital, where he died, January 4, of acute dilatation of the heart, following pneumonia

Frederick Harris Morse, Boston, University of the City of New York Medical Department New York, 1881, member of the Massachusetts Medical Society, aged 81, died, January 14, in Wollaston, of arteriosclerotic heart disease

James I Campbell, Norwood N C (licensed in North Carolina in 1898), member of the Medical Society of the State of North Carolina, aged 63, died January 15, at Charlotte, of a self-inflicted wound of the jugular vein

Francis Ashbell Pomeroy, Cheney, Wash., Long Island College Hospital, Brooklyn, 1883, formerly mayor and member of the school board, aged 89, died, January 31, in Tacoma, of hypertrophy of the prostate and uremia

Charles Depew Ver Nooy @ Cortland, N. Y., Syracuse University College of Medicine, 1892, part owner of the Cortland Sanitarium, president of the board of education, aged 69, died, January 20, of coronary occlusion

Martha J. Short Wright, Rolla, Mo., Ensworth Medical College, St. Joseph, 1892, member of the Missouri State Medical Association, aged 76, died, January 10, of a spinal injury received in a fall twelve years ago

Joseph Thomas Slattery, Dunlap, Iowa, John A. Creighton Medical College, Omaha, 1909, member of the Iowa State Medical Society, served during the World War, aged 57, died, January 1, of mitral insufficiency

Robert Ellsworth Wells @ Nashport, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor 1907, served during the World War, aged 52, died, January 3, of a self-inflicted bullet wound

William George Raymond Jotcham, Minna, Nigeria, Africa, McGill University Faculty of Medicine, Montreal, Que., Canada, 1935, a medical missionary, aged 25, died, January 10, of cerebrospinal meningitis

Albert William Tiedeman @ Baker, Ore., University of Oregon Medical School, Portland, 1914, member of the school board, on the staff of St. Elizabeth Hospital, aged 53, died, January 3, of angina pectoris

Eugene Walker Hart, Dadeville, Ala., Baltimore University School of Medicine, 1891, member of the Medical Association of the State of Alabama, aged 74, died, January 27, of chronic cardiorenal disease

Henry Jacques Ravold @ St. Joseph, Mo., Homeopathic Medical College of Missouri, St. Louis, 1886, member of the Radiological Society of North America, aged 74, died, in January, of coronary occlusion

Walter George Gonzales, Hoboken, N. J., Georgetown University School of Medicine, Washington, D. C., 1925, on the staff of St. Mary's Hospital, aged 38, died, January 17, of lobar pneumonia

Lake Lewis Starkey @ Harlingen, Texas, Birmingham (Ala.) Medical College, 1902, on the staff of the Valley Baptist Hospital, aged 61, died, January 2, of injuries received in an automobile accident

William Ernest Nelson, Westmount, Que., Canada, McGill University Faculty of Medicine, Montreal, 1903, served during the World War, aged 56, died, January 13, in the Montreal General Hospital

William John O'Donnell @ Buffalo, Niagara University Medical Department, Buffalo, 1897, on the staff of the Providence Retreat, aged 63, died, January 7, of acute appendicitis and septicemia

Braxton Bragg Pugh, Uniontown, Ala., Medical College of Alabama, Mobile, 1889, member of the Medical Association of the State of Alabama, aged 73, died, January 20, of coronary thrombosis

Calvin O. Sones, Morrison, Ill., State University of Iowa College of Medicine, Iowa City, 1886, member of the Iowa State Medical Society, aged 84, died, January 12, of coronary thrombosis

Ralph Lemen Taylor, Long Beach, Calif., University of Denver Medical Department, 1893, formerly city health officer of Long Beach, aged 66, died, January 8, of cardiac decompensation

John Decard Hall, Chavies, Ala., Southern Medical College, Atlanta, Ga., 1892, aged 69, died, January 31, in the Erlanger Hospital, Chattanooga, Tenn., of carcinoma of the prostate

John C. Scott, Lebanon, Mo., Indiana College of Medicine and Midwifery, Indianapolis, 1888, member of the Missouri State Medical Association, aged 66, died, in January, of pneumonia

John W. Wood, Boiling Springs, N. C., Louisville (Ky.) Medical College, 1892, member of the Medical Society of the State of North Carolina, aged 66, died, January 15, of pneumonia

Joshua B. Thurman, Atlanta, Ga., Bellevue Hospital Medical College, New York, 1886, aged 79, died, January 31, of shock, following prostatic resection for adenoma of the prostate

Silas T. Richman, Columbus, Ind., Medical College of Indiana, Indianapolis, 1883, Northwestern University Medical School, Chicago, 1899, aged 85, died, January 3, of uremia

J. Leonard Lucas, Edwards, Miss., Meharry Medical College, Nashville, Tenn., 1906, aged 52, died, January 23, of septicemia with stricture of the urethra and urinary obstruction

George Wellington Good, Berwyn, Ill., Jenner Medical College, Chicago, 1908, at one time postmaster of Laverne, aged 69, died, January 10, of chronic myocarditis and nephritis

Jean Jacques Lamontagne, Montreal, Que., Canada, University of Montreal Faculty of Medicine, Montreal, 1932, on the staff of St. Luke's Hospital, aged 28, died, Dec. 23, 1936

Joseph Keefer Fisher, Sunbury, Pa., Temple University School of Medicine, Philadelphia, 1920, formerly county coroner, aged 41, died, January 29, of pulmonary tuberculosis

George S. Townsend, Sylvania, Mich. (licensed in Michigan in 1900), for many years member of the school board, aged 90, died, January 12, of uremia and arteriosclerosis

Samuel Henry Roberts, Skillman, N. J., Cornell University Medical College, New York, 1936, aged 27, died, January 29, of an overdose of phenobarbital, self-administered

William Henry Hanchette, Los Angeles, Chicago Homeopathic Medical College, 1879, aged 84, died, January 15, in a hospital at San Pedro, of carcinoma of the prostate

Philemon Roy @ St. Paul, Drake University Medical Department, Des Moines, Iowa, 1896, aged 68, died, January 21, at McAllen, Texas, of coronary thrombosis

Curtis Albert Tucker, Springfield, Mo., American Medical College, St. Louis, 1903, served during the World War, aged 65, died, January 3, of coronary thrombosis

Walter N. Sherman, Pasadena, Calif., Indiana Medical College, Indianapolis, 1875, aged 83, died, January 15, in the Las Encinas Sanitarium, of chronic myocarditis

William Albert Smith, Wichita, Kan., Medical College of Ohio, Cincinnati, 1897, aged 65, died, January 31, of obstructive jaundice and carcinoma of the pancreas

John J. Arberry, San Francisco University of Louisville (Ky.) Medical Department, 1891, aged 74, died, Dec. 19, 1937, of hemiplegia and cerebral arteriosclerosis

Hall Vestal, Richmond, Calif., Cooper Medical College, San Francisco, 1900, aged 63, died, Dec. 2, 1937, in a hospital at Berkeley, of carcinoma of the bladder

Richard Andrew Elliott, Avon, Mass., Long Island College Hospital, Brooklyn, 1896, aged 71, died, January 11, in Boston, of hypertrophy of the prostate

Charles Edward Chapman, Mobile, Ala., Medical Department of the University of Alabama, Mobile, 1900, aged 59, died in January of cerebral hemorrhage

Joseph Francis Schlotterer, Philadelphia, Medico-Chirurgical College of Philadelphia, 1905, aged 56, died, January 5, of chronic myocarditis and nephritis

T. G. Harriman, Long Beach, Calif., Northwestern University Medical School, Chicago, 1901, also a lawyer, aged 63, died, January 18, of arteriosclerosis

Edwin Kendall Richardson, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, Toronto, 1895, aged 68, died, January 4, of pneumonia

Phileas Desmarais, Pascoag, R. I., School of Medicine and Surgery, Montreal, Que., Canada, 1899, aged 64, died, January 15, in a hospital at Howard

George Ernest Darrow, Los Angeles, John A. Creighton Medical College, Omaha, 1907, aged 62, died, Dec. 14, 1937, of carcinoma and pneumonia

Lon W. Pulley @ Trinidad, Texas (licensed in Texas under the Act of 1907), aged 62, died, January 1, in a hospital at Dallas, of coronary occlusion

J. Albert Beauchamp, St. Cesaire, Que., Canada, University of Montreal Faculty of Medicine, Montreal, 1921, aged 42, died, January 14

Robert H. Peacock, Winter Haven, Fla., Hahnemann Medical College of Philadelphia, 1881, aged 79, died, Nov. 28, 1937, at Lake City

Edwin V. Hervey, Indianapolis, Medical College of Indiana, Indianapolis, 1886, aged 80, died, January 16, of cerebral thrombosis

Frank R. Hill, La Mesa, Calif., Pulte Medical College, Cincinnati, 1884, aged 81, died, January 9, of cerebral hemorrhage

REGULATIONS FOR PREVENTION OF EPIDEMIC DIARRHEA OF THE NEWBORN

To the Editor—The regulations for conduct of maternity divisions in New York City stated by Dr William H Best (THE JOURNAL, April 9, p 1155) indicate that New York has done an excellent piece of work which should be of value to the rest of the country. The following constructive suggestions concerning the New York rules are offered with the hope that not only New York but also other interested groups will, with equal candor, criticize Chicago's regulations, thereby leading to the formation of the best possible type of procedures.

The New York regulations were established 'after numerous conferences with leading obstetricians, pediatricians, representatives of the county medical societies, the Academy of Medicine, and various hospital, medical and nursing groups. The Chicago regulations were established by those groups most interested in this type of work, namely, representatives of the Chicago Medical Society, Chicago Gynecological Society, Chicago Hospital Association, Infant Welfare Society, Chicago Hospital Council, Catholic Hospitals of the Archdiocese of Chicago, American College of Surgeons, Chicago Pediatric Society making up the Joint Maternal Welfare Committee of Cook County, and the Chicago Board of Health. It was the purpose of the group to formulate regulations which they thought would be practical so as not to interfere with the successful conduct of a hospital, and at the same time not so lenient that preventable morbidity and mortality might occur.

Regulations which are satisfactory and reasonable and which are developed by the cooperative effort of interested groups are much more likely to be successfully carried out than those which are arbitrarily set up and enforced.

New York's regulation 1 (a) does not provide for the isolation of a mother delivered elsewhere in an institution than in the clean maternity division. For example, a precipitate delivery might occur in a corridor or an unclean operating room. Such a case should be isolated as provided in the Chicago rules.

New York's regulation 1 (b) requires that there be two delivery room units, one for normal and one for infected cases. Chicago's regulations permit the delivery in infected cases in a private room, properly equipped, if a second delivery room is not available.

New York's regulation 1 (c) would require the delivery room to be on the same floor as the rest of the obstetric division.

Chicago's regulations allow the delivery room to be elsewhere than on the obstetric floor if the patient is properly safeguarded while being moved from the delivery room to the obstetric floor. By so doing, extensive reconstruction of the existing building may be avoided.

New York's regulation 2 (b) requires that an isolation nursery be maintained. Chicago's regulations provide that an isolation nursery be maintained and, in addition, that a second clean nursery be available when several cases of diarrhea occur. Thus infected infants may be isolated in one nursery, healthy contacts isolated in a second nursery, and nonexposed and noninfected newborn infants placed in still another nursery. Experience with outbreaks of infection in newborn nurseries has shown that morbidity and mortality are high because of failure to recognize what is occurring and to isolate immediately the infected infants. Furthermore, contacts also must be isolated. In our experience, if contact with exposed infants is avoided, outbreaks may be prevented so that closing of the maternity ward is obviated. When a case of diarrhea occurs in an institution in the interim of deciding whether an epidemic is really starting and whether the maternity service should be closed,

it is important that nonexposed newborn infants be kept out of contact with those who have been exposed.

New York's regulation 2 (a) requires that every hospital shall have a nursery for the care of premature and immature infants. There are many institutions in which births of premature infants occur no more frequently than once every two or three weeks, if that often. Chicago's regulations permit the care of premature infants in the normal newborn nursery, provided there is adequate specially trained nursing personnel throughout the twenty-four hour period and satisfactory equipment, which are felt to be the most important factors in the care of premature infants. Chicago's regulations do not require that every hospital have a premature nursery. They permit the transportation of premature infants in a specially constructed incubator ambulance to some central premature station, if the hospital does not wish to have the expense of maintaining a premature nursery.

New York's regulation 2 (b) does not require that an infant, delivered elsewhere in an institution than in the clean maternity section, be isolated. Chicago's regulations provide for such isolation, as well as for the isolation of infants exposed to communicable infections, particularly impetigo of the newborn or epidemic diarrhea of the newborn, since such infants may contract the disease and, unless isolated, may expose others.

New York's regulation 2 (d) does not require lined bassinets. Chicago's regulations do, to help prevent injury to babies.

New York's regulation 2 (d) does not require that when a carrier system is used there be redraping of bassinets before infants are put into them, nor does it specifically require washing of the hands before taking each baby out of the carrier. Chicago's regulations provide for such redraping and hand washing, as well as for arrangements to have one nurse constantly in attendance on the infants in the bassinets on the carrier to prevent contact with visitors or other possible sources of infection.

New York's regulations 2 (k) and 4 (d) require sterilization of bottles twice, once in the nursery and again in the formula room. Chicago's regulations require that the bottles be cleaned in the nursery and sterilized in the formula room.

New York's regulation 2 (l) permits the use of cresol for the cleansing of equipment, such as the stethoscope bowl which comes in contact with the infant's skin. Since burns have resulted in some instances from the use of cresol, Chicago's regulations provide for the use of safe antiseptics only for such purposes.

New York's regulation 4 does not require running water with foot control in the formula room suite. This will make proper hand washing difficult in the formula room. Chicago's regulations require this.

New York's regulation 4 (c) does not require that sugar solutions be stored in individual bottles and prepared fresh daily, as is required by the Chicago rules. In epidemics of diarrhea which have occurred in newborn nurseries, in a number of instances it has been found that sugar solutions, dextrose or betalactose, have been stored in bulk and used for the babies. In Chicago nurseries, tests of such solutions stored in bulk have revealed their bacterial count to be exceptionally high.

New York's regulation 6 requires disinfectant solutions to be used after hand washing, but these are not required in Chicago's regulations.

New York's regulation 6 does not specify running water with arm, knee, or foot control devices. Chicago's regulations specify this. Without running water operated in this way, proper and thorough hand washing is not possible.

New York's regulation 7 (c) requires scrubbing and the wearing of rubber gloves or the use of forceps to change a nipple on a bottle. The Chicago regulations rely on thorough scrubbing of the hands.

New York's regulation 8 requires that the newborn nursery be under the supervision of the obstetric or of the pediatric

service The Chicago regulations specifically require that a single physician be in charge of the nursery and responsible for its conduct, which seems more satisfactory from the standpoint of enforcement

New York's regulation 10 (a), to be adequately carried out, would require prostatic examination for all male individuals, and urinary and stool examinations on all personnel on duty in the maternity division Furthermore, to be of value, such examinations would have to be repeated at monthly intervals Chicago's regulations require nose and throat cultures, Dick and Schick tests, and examination for focal infections Attention is focused on infections which might be responsible for outbreaks of disease in the maternity division and nursery, such as tonsillar or sinus infections, and diarrhea, as well as on existing or recent active communicable infection in potential carriers

New York's regulation 13 (a) requires that personnel "shall wash their hands with soap and hot water and immerse them in a suitable disinfectant solution" Chicago's regulations do not require disinfectant solutions but stress thorough hand washing Disinfectant solutions are not effective for hand sterilization There are many who believe that when disinfectant solutions are available there is carelessness in hand washing while, if they are not provided, hand washing is more thorough and satisfactory

New York's regulation 13 (a) makes no provision as to the drying of the hands Chicago's rules require drying on individual towels

New York's regulation 13 (b) requires that physicians visiting mothers in wards wear a face mask, cap and gown This is not required in the Chicago regulations, since it is felt that it will do little to prevent infections and that it is an unnecessary hardship to wear a mask, cap and gown just to visit a patient

New York's regulation 13 (d) requires a mother to wear a face mask during the time she is breast feeding her baby By the Chicago regulations, the mother is required to wear a mask only when she has an infection of the upper part of the respiratory tract

New York's regulation 14 (a) requires that a minimum of visiting be permitted but no statement is made concerning what is considered a minimum of visiting The Chicago regulations specifically permit two visitors a day, exclusive of the husband

The Chicago regulations require each hospital to establish its own adequate obstetric staff and requirements for the calling of consultations, and for the conduct of maternity divisions which will prohibit the abuse of oxytocics, analgesics and operative procedures during deliveries It is hoped that these regulations will aid in reducing the number of deaths from cerebral hemorrhage asphyxia, and prematurity The New York regulations do not require these things

The Chicago regulations will tend to prevent not only gastrointestinal infections but all infections of the newborn and will tend to protect the mother, fetus and newborn from many disasters other than those due to infectious agents

HERMAN BLUMENBERG, M.D. Chicago
President Board of Health

BENZEDRINE SULFATE—A WARNING

To the Editor—I cannot refrain from saying a word of approval with regard to your editorial on Benzedrine Sulfate—A Warning' I am a neurasthenic doctor 65 years of age and when some months ago a sample of benzedrine sulfate fell into my hands with the accompanying literature I had to try it It worked like a charm if I got up in the morning feeling somewhat dragged out and took a tablet of benzedrine sulfate I felt pretty well all day and could do my work without tiring, the result was that I took it almost daily Before

very long I got so I couldn't sleep and couldn't eat I have never been much of an eater but could eat reasonably well It never occurred to me that the benzedrine sulfate could be at the bottom of it and I had a gastrointestinal series run and a rectal examination made, it finally dawned on me that the benzedrine sulfate had something to do with it and I promptly stopped it I can now sleep pretty well but have not as yet recovered my appetite I am glad once more to confirm the wisdom and the conservative attitude of THE JOURNAL

DONALD MACLEAN, M.D., Reno, Nev

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST

ANESTHESIA FOR DELIVERY IN HOME

To the Editor—What type of anesthesia would be best to use for delivery in the home in a rural community? Please give information as to dosage method of administration time for giving length of time that it is effective, and any other helpful information M.D., California

ANSWER—Satisfactory and safe analgesia in labor, particularly for patients to be delivered in the home, is as yet not available It must be realized that analgesic drugs of all kinds are likely to add to the complications of labor and delivery Undoubtedly, some form of analgesia must be used in the majority of cases It is thus necessary to acquaint oneself with one method, to learn its limitations and the complications that are likely to result from its use and to be prepared to meet these when they occur

Morphine and scopolamine properly administered probably offer the safest analgesia for the patient to be confined in her home In the usual primiparous labor morphine from 0.01 to 0.016 Gm (one-sixth to one-fourth grain) and scopolamine from 0.00025 to 0.0005 Gm ($\frac{1}{2000}$ to $\frac{1}{400}$ grain) can be given when the cervix is completely effaced and dilated sufficiently to admit two or three fingers (from 3 to 4 cm) In the large majority of cases this will be sufficient to carry the patient to the end of the first stage of labor Some form of inhalation anesthetic usually ether, can be used during the second stage It is rarely advisable to repeat these drugs unless the labor is unusually prolonged, in which case a much smaller dose should be used It has been the experience of some that scopolamine in ampules is more efficacious than the tablets

The only serious complication that may result from the use of these drugs is morphine narcosis of the baby This is more likely to occur when the drug is administered less than four hours before the birth of the child It is likewise more apt to occur following a difficult delivery or in the event that the baby is premature It is most important to learn how to resuscitate asphyxiated babies The simplest and most effective procedure is to clear the air passages by means of a hard rubber catheter and to carry on respiration artificially by means of this catheter until breathing has been well established The baby should be kept warm during the process of resuscitation If these measures are carried out, no baby need be lost as a result of the analgesia administered to the mother (Shute Evan and Davis M.E. The Effect on the Infant of Morphine Administered in Labor, Surg, Gynec & Obst 57 727 [Dec] 1933)

VITAL STATISTICS

To the Editor—What do the figures on vital statistics mean? When a death rate is given does that refer to the number of deaths from a given disease according to the whole population of the town at the time of the report or does it refer to the number of deaths according to the incidence of the disease? M.D. New York

ANSWER—The death rate of a city is the number of deaths divided by the population It is usually expressed per thousand or per hundred thousand persons is frequently on an annual basis may be for specific population groups (by age sex or color) and may or may not be by diagnosis The other rate referred to (the proportion of cases which terminated fatally) is customarily termed a case fatality rate, not a death rate

POSSIBLE CAUSES OF RECURRING ITCHING AND SWELLING FEET

To the Editor—A white man aged 45 for the past three years has been having a periodic recurrence of swelling and itching of the feet. At regular intervals of about three weeks he notices intense itching on the plantar surface of the left foot which spreads over the entire surface and at the same time the foot swells gradually reaching about twice the normal size. The swelling is firm and boardlike. The swelling and itching reach a maximum in about forty to sixty hours and subside rapidly in from six to ten hours. There is no redness and apparently no thermal disturbance locally. There is a systemic reaction consisting of a rise of temperature to 100 or 100.2 F, loss of appetite, general aching and malaise. Between attacks he feels fine in every way. The patient served twelve years in the United States Navy prior to 1931. Most of this time was spent in the tropics. There has been no serious illness previous to the present condition. Seasons of the year and geographic locations have no effect on the severity or periodicity. Repeated examinations reveal nothing abnormal including the blood count, condition of the heart, blood pressure, lungs and prostate and x-ray examination of the gallbladder and the gastrointestinal tract. I would appreciate any information on the nature of this condition or any suggestions regarding further study.

M D Missouri

ANSWER—The paucity of symptoms makes diagnosis difficult and necessitates the consideration of diagnoses that seem remote possibilities. The swelling of the foot suggests (1) local interference with blood or lymph circulation, (2) local infection or (3) general infection with local manifestations.

The regularity of the attacks and the absence of local pain, tenderness and redness make it difficult to ascribe the swelling to recurrent attacks of phlebitis of the deep veins. Intrapelvic interference with circulation seems also unlikely, but the pelvis should be examined carefully for anything that might cause mechanical obstruction, and a Frei test for venereal lymphogranuloma should be made.

In the temperate zone by far the commonest cause of periodic swelling of the foot and leg is the erysipelas-like infection, said by some to be due to the Fehleisen streptococcus, which causes elephantiasis. The inflammatory attacks come on at irregular intervals and soon lead to permanent enlargement.

Infection with a filaria is supposed to be the common cause of elephantiasis in the tropics, though there are some who dispute this. Like the form seen in the temperate zone, the attacks of fever and inflammation occur at irregular intervals and soon lead to permanent enlargement, attaining immense dimensions in many cases. In spite of these objections, the blood of the patient should be examined for filaria during one of the febrile attacks.

Undulant fever and malaria, when mild, are so variable in their manifestations that they come under suspicion. Three years is a long course for undulant fever and the three year interval between the return of the patient from the tropics and the onset of the present trouble seems a long period of latency for malaria, yet the blood should be examined for plasmodia during a febrile paroxysm. The intradermal test and Huddleson antigen agglutination test for undulant fever also should be made. The differential white count should be studied with these possibilities in mind. Both cause a leukopenia with relative increases of the mononuclear cells, but in undulant fever the lymphocytes are increased, while in malaria the relative increase is in the large mononuclears.

Finally, it is a good rule to think of syphilis, regardless of the difficulty of explaining the symptoms in accordance with the usual manifestations of the disease. Hepatic syphilis is known to cause periodic febrile attacks. This possibility should be investigated.

DANGERS FROM BURNING MOTION PICTURE FILMS

To the Editor—If a motion picture film ignites while the operator is showing it what other dangers are present aside from the flames and poisonous gases? What precautions can be taken?

M D Wyoming

ANSWER—Poisonous gases likely to arise in connection with the burning of motion picture films are the oxides of nitrogen, if cellulose nitrate films are used and carbon monoxide. The so called safety films are believed to be cellulose acetate. In addition there may arise some carbon dioxide and in the case of the nitrate films gases of complex nature are derived from the acetate component. Most states and cities require booting for housing motion picture operations, particularly if the machines are located in the same rooms occupied by public audiences. This is especially true if the films used are of the cellulose nitrate variety. These booths while serving the interests of the audience may increase the exposure for the operator since the gases created are confined to small spaces. By way of protection the following is suggested: 1 The booths particularly if small should be exhausted in order to remove excessive heat under normal conditions and to aid in the removal of injurious

gases in the event of fire. 2 Fire extinguishers should be available, but it is to be remembered that the carbon tetrachloride type of fire extinguishers may lead to dangerous carbon tetrachloride vapors. Further, there is some belief that carbon tetrachloride in contact with highly heated surfaces may lead to the formation of phosgene, which is of course highly toxic and dangerous. 3 Emergency respirators are available through purchase, which should be worn by operators when confronted with a fire emergency. 4 Under some, but not necessarily all, circumstances a sprinkler head system or analogous equipment may be called for, either by law or by good practice for the combating of this type of fire.

BITING LIPS AND CHEEKS

To the Editor—I have had a lifelong habit of biting the lips and cheeks and stripping off the mucous membrane. What can be done to prevent this? Would it be safe to put a clip of some sort over a tooth so as to prevent complete occlusion? Is there such a device on the market? If so where should I inquire for it?

M D New Jersey

ANSWER—The habit of biting the lips and cheek is decidedly dangerous and should not be allowed to continue. The continuous irritation produced in this way may set up serious pathologic conditions. The first step in the consideration of such a case should be the construction of accurate plaster or stone models made from plaster impressions of the dentures. A careful study of these may show conditions that invite the execution of the habit. Judicious grinding of the teeth may make the execution of the habit difficult enough to effect a cure.

Such lip and cheek biting is often to be considered as a nervous habit and should be corrected under the advice of a neurologist. Such habits are unconsciously executed and sometimes they can be cured by consciously executing them before a mirror regularly every day for a time, the object being to bring the muscles and nerve tracts involved in the execution of the habit under conscious control and thereby breaking up the unconscious execution. If no other method is available, probably removable appliances should be made that can be worn on the teeth so as to make the execution of the habit impossible. These could be made only for the individual patient and by a skilful dentist. They should be used only as a means of breaking the habit.

MANAGEMENT OF MYOPIA

To the Editor—A patient was discovered to have pronounced myopia of the left eye at the age of 4, so that normal vision (20/20) could be obtained by a lens —13D. The right eye was normal. This patient never had binocular vision and still almost exclusively uses her right eye. She wore eyeglasses on the advice of an eye specialist and the strength of the lens of the left eye was gradually worked up to —13. In the meantime the right eye became myopic and last year the correction for the right eye was —1.5 (the patient is now 13 years old). At present the eye specialist has prescribed the lens —3. He insists that she shall always use her glasses for far and near work and is of the opinion that she must always have eyeglasses to obtain vision 20/20 in each eye. When I expressed my fear that the strain of accommodation in near work would aggravate the myopia he told me that if she should not use the eyeglasses and should do her work without using much accommodation her eye muscles would become atrophied. Now another eye specialist has examined the patient and tells me that 1 She should not have had any correction for the left (myopic) eye. This eye would not become atrophied from lack of use as the previous specialist told me. The correction of this eye tend to make the right eye myopic. 2 The patient should have as little correction of vision as possible for comfortable street use. She should do most of her writing and reading without the eyeglasses. 3 Her eye muscles would not become appreciably atrophied and her myopia would not progress or would progress much slower if she should follow this advice. Please advise me as to what course the patient should follow and whether the opposing advice is due to a difference of personal opinion of these two eye specialists or whether there are two different schools in ophthalmology with opposite approaches to guiding a case of myopia.

M D New York

ANSWER—This case exhibits an essential difference of opinion between ophthalmologists with reference to several points about myopia. First one would agree with the physician who prescribed correction for the eye with high myopia in infancy. While it is not certain that the vision would have deteriorated at this age if the correction had not been prescribed, an eye that is uncorrected is probably more liable to develop convergent or divergent squint than if it is corrected. Many ophthalmologists might not agree with him, however, that the patient must use the full correction for both eyes at all times for fear the eye muscles will become atrophied. On the other hand there is no evidence that the myopia will become aggravated by wearing this correction. In other words, it would probably be advisable that the full correction be worn a considerable part of the time especially if the patient does not notice any discomfort on close work. If discomfort is noticed

on close work the correction may be cut down or the patient may go without glasses for this purpose alone without harmful effect. It is not likely that wearing or going without the glasses will have any effect on the progress of the myopia, which will proceed to a certain point in any case and then stop. Conceivably a large number of ophthalmologists might disagree with the opinion here expressed, the answer can only reflect what seems to be a sound point of view.

POSSIBLE SYMPTOMS FROM COPAVIN

To the Editor—The preparation copavin Lilly used for the treatment of common colds, has been written up several times in THE JOURNAL. Each capsule is said to contain one fourth grain (0.016 Gm.) of papaverine and one fourth grain of codeine. Several patients taking one capsule every two hours (five in twenty-four hours) have complained of nausea without vomiting which discomfort was relieved after discontinuance of the treatment and of being dizzy and light headed from which condition relief is obtained soon after treatment is discontinued. In a clinic the percentage of cases showing either symptom or both is less than 1. Two months ago a husky man with a forty-eight hour old common cold was given copavin. After two or three doses he became nauseated but did not vomit. The medicine was stopped. The next day the nausea continued and another doctor reports that he is still suffering from the effects of the treatment (although neither he nor the patient knows what drugs were originally prescribed). The man lost three days from his work immediately after the nausea began. Have you had similar complaints and inquiries? Can either papaverine or codeine or the combination cause nausea that could require treatment for two months after the administration of copavin? My own interpretation is that he had a cold not limited to the upper respiratory tract but involving the gastrointestinal tract and the nausea may have developed in spite of medication. Will you kindly advise me?

M D New York

ANSWER—Copavin is the proprietary name under which Eli Lilly markets under license of the University of Minnesota a mixture of codeine sulfate and papaverine hydrochloride.

Codeine is rapidly absorbed from the bowel and rapidly excreted to the extent of 80 per cent or more in the urine. Although codeine has only a slight tendency to cause digestive derangements, cases have been reported in which single doses of from 100 to 200 mg. (from 1½ to 3 grains) have caused marked nausea. The presence of papaverine, which is not known to produce nausea in therapeutic doses of from 30 to 60 mg. (one-half to 1 grain), may potentiate the action of codeine.

The patient received from 30 to 45 mg. (one-half to three-fourths grain) of each of the drugs. In very susceptible individuals this could cause nausea, but owing to the rapid elimination of the drugs (assuming no impaired kidney function) it is a perfectly sound assumption that the continued nausea is not due to the codeine phosphate-papaverine hydrochloride mixture administered two months previously.

ATTACKS OF APNEA IN INFANT

To the Editor—A boy aged 22 months has been subject to attacks of complete cessation of breathing since returning home from the hospital following a normal delivery. The duration of the attacks has tended to decrease. A variety of causes will bring on an attack such as crying, falling and hurting himself or being undressed for an examination by the doctor. An attack begins by his taking a deep breath and holding it. During the period of absent breathing the child lies very quiet although occasionally he will move his limbs. He becomes cyanotic. Then he takes a deep breath lies quiet again as if unconscious with shallow breathing and frequently micturates and defecates. Then he takes another very deep breath begins to cry or goes on with his play although very pale for an hour after. He appears very tired after such an episode. The attacks may occur several times a day or be absent for a week. Their duration is from a few seconds to a full minute. At birth he weighed 5 pounds 2½ ounces (2,340 Gm.). At 22 months he weighs 22 pounds (10 Kg.). He is small for his age but his body is well proportioned. Development has been normal. He was slow in learning to sit and walk but was within normal limits. His intelligence is normal. A consultant discovered a soft apical systolic murmur but I have been unable to confirm this. The child is subject to colds during which wheezing breath sounds can be heard. Examination is otherwise negative. The family history is negative. Please comment on diagnosis, prognosis and treatment.

M D New York

ANSWER—The case offers an interesting diagnostic problem. The episodes are strongly suggestive of breath holding. The early onset is a point against this but the spells described are characteristic of this disorder. Other conditions that must be considered here are: 1. Congenital heart disease though the lack of constancy of the murmur described would make this diagnosis questionable however an x-ray examination should be made of the heart, which would at the same time also show the size of the thymus. 2. Hypoglycemia which not infrequently results in spells simulating the signs described and the careful study of the diet and the blood sugar are indicated. 3. Tetany. Blood calcium determinations should be made at

the same time that the tests for hypoglycemia are made. A dextrose tolerance test would also be of value in considering the possibility of hypoglycemia. 4. The possibility of an old birth hemorrhage affecting the respiratory center or similar changes resulting in minor epileptic attacks. There should be some more definite neurologic signs if this is a factor. Since no definite diagnosis can be made from the symptoms presented the treatment must be expectant and the result will depend on the underlying cause of the clinical manifestations. In view of the uncertainty of the cause, the prognosis had best be guarded. If the child is a breath holder, the prognosis is good but any of the other possibilities might not be so favorable. There is no medical therapy for breath holding. The prognosis is excellent and the condition usually disappears after the second year.

INTERSTITIAL KERATITIS

To the Editor—A man aged 23 came under my care on July 13, 1931, for treatment of an acute inflammatory condition of the cornea of his right eye, characterized by a flake-like cloudiness of the nasal third and involving the deeper layers. The corneal epithelium was intact and there was no vascularization at this time but as the cloudiness advanced to involve the whole cornea a few deep blood vessels were seen to grow in from the limbus. The vascularization was of a broom type and cells were observed in the anterior chamber. Vision was reduced consistently with the edema of the cornea. A search for foci revealed a four plus Wassermann reaction. There were no other foci. History disclosed that the father has been under antisyphilitic treatment within the last few years as the result of a coincidental finding of a positive blood Wassermann reaction. A diagnosis of acute interstitial keratitis of syphilitic origin was made on the history, serologic tests and character of the lesion. The patient was immediately treated with intramuscular injections of a bismuth compound supplemented by silver arsphenamine intravenously along with local treatment to the eye consisting of yellow mercuric oxide atropine and heat. This eye responded quite well to treatment and at the end of two months his vision was normal and the only evidence of the disease is a few flake-like opacities visible under the slit lamp and two or three short deep blood vessels protruding 5 mm. in from the limbus. The center of the cornea was not vascularized. At about the time the right eye had cleared in spite of treatment the left eye showed a similar cloudiness of the cornea at the temporal limbus and there is one deep blood vessel growing in at this stage. There are a few cells in the anterior chamber. The cloudiness is advancing at each subsequent visit to my office. I have thought of giving intravenous typhoid therapy but I have not started it. The second eye has now been involved for four days and the cloudiness has extended about 4 mm. from the temporal limbus. Will you kindly offer this for the opinions of other ophthalmologists? I shall appreciate their recommendations. I should also like to know how frequently the second eye is involved in cases in which intensive antisyphilitic treatment has been given over a two months period prior to its inception in the other eye. Please omit name.

M D New York

ANSWER—Interstitial keratitis is as in this case, almost always bilateral. Involvement of the second eye may occasionally be prevented by energetic antisyphilitic treatment, begun while the process is still unilateral. In view of the fact that the right eye in this patient has cleared almost completely and that the present involvement of the left eye is apparently minimal, it seems likely that a continuation of energetic combined antisyphilitic treatment with an arsenamine bismuth compound and potassium iodide will clear up the process completely in both eyes.

Interstitial keratitis differs from all other inflammatory lesions of syphilis in the extreme slowness with which it responds to chemotherapeutic treatment. The subsidence of the acute inflammatory reaction usually takes six weeks or longer. The duration of healing may be lessened and the possibility of complete healing very much enhanced by means of combined nonspecific treatment and chemotherapy. The best procedure would be induced malaria followed by energetic chemotherapy. Failing this, intravenous injections of typhoid vaccine sufficient in dosage to produce a temperature of from 103 to 105 F., may be actually combined with chemotherapy, the arsenical injection being given at the height of the fever.

CONVULSIONS DURING ANESTHESIA

To the Editor—What is known concerning convulsions during ether and nitrous oxide anesthesia? Is there any adequate therapy for such a condition? Also I should appreciate a few references on the subject. M D New York

ANSWER—The literature concerning convulsions during anesthesia has been presented in considerable detail by Lundy (Convulsions Associated with General Anesthesia, *Surgery* 1: 66 [May] 1937). This article included a complete bibliography on the subject. Another article (Lundy, J. S. and Lundy, E. B. General Anesthesia Complicated by Convulsion, *THE JOURNAL* March 20, 1937, p. 971) was practically an abridgment of the article in *Surgery* without however the tabulated information concerning the 150 cases that were considered there.

An informing article on this subject was one by E C Rosenow and R M Tovell (Etiology of Muscular Spasms During General Anesthesia, *Am J Surg* 34 474 [Dec] 1936)

The therapy for the condition, at present, is the use of an antispasmodic. For this purpose the soluble barbiturates given intravenously are the first to come to mind and without doubt are the best and most available ones. It should be possible, and often is, to control the convulsions until the effect of the anesthetic wears off, and it should be possible even for days if necessary, as is possible in treating tetanus, until the disease has run its course.

Doubtless the authors will be glad to furnish reprints of the articles referred to.

Council on Medical Education and Hospitals

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Thirty Fourth Annual Meeting held in Chicago Feb 14 and 15 1938

(Continued from page 1217)

DR J W BOWERS, Fort Wayne, Ind., in the Chair

JOINT SESSION OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS AND THE FEDERATION OF STATE MEDICAL BOARDS

FEBRUARY 15—MORNING

Hospital Internships as a Requirement for State Registration

DR WINFORD H SMITH, Baltimore. I addressed a letter to a number of hospitals and asked the following questions: 1 Are the internships in your hospital rotating in type? 2 Do you believe that the rotating internship is the most valuable type to the individual? 3 Do you think this type of internship should be the only type recognized by state boards of licensure? 4 Please discuss any phases of this problem which occur to you. The answers received indicate clearly that there is a large body of opinion definitely opposed to the present demands of boards of licensure in some states. It may be said that these boards are merely carrying out the law and that in many instances the present boards are not responsible for the law. That is undoubtedly true, but it is also probably true that in some states those boards have some discretion in the matter and could be more liberal than they are. Furthermore, the board of licensure is probably the best body to undertake to bring about a change in the law where a change is desirable.

Hospitals owe a duty to the public to provide the best type of service to their patients. That is their main function. The requirement of a fifth, or intern, year indicates that in some states it is felt that a four year course in medicine is not sufficient to fit a man to practice medicine. Why make the hospital responsible for completing his training by methods which result in sacrificing the type of organization which is for the best interest of the patients? Should the aim be solely the training of general practitioners? If so, then the requirement should be a two year rotating service, at least, for a one year rotating service will not yield the result desired. We must recognize that many graduates intend to specialize. Is it not desirable, therefore, to recognize types of intern service which promote such training to the fullest degree? There are many competent authorities who feel that it is desirable. It is my opinion that boards of licensure might better decide what hospitals are capable of giving interns an experience of sufficient value to qualify them for registration, recognizing that this may be accomplished by various types of service.

I recognize that it is necessary to require a rotating service in some hospitals perhaps in the majority of hospitals, because the majority of general hospitals are too small to offer any other type of internship which would be worth while. I do not claim that the straight service is the only type that should be recognized. Each type has its place. A straight service internship in a teaching hospital of one year's duration of the sort I have in mind is a more valuable experience than a one year rotating internship in a small hospital of the nonteaching variety. An exposure to four or five different fields of medical work for a period of from two to three months each does not of itself offset the advantages which straight service internships in teaching hospitals enjoy. I believe that men trained for twelve months on a straight service, under conditions I have outlined are safer men than one who has had a hodgepodge experience with a little of everything and not much of anything. I plead for a more liberal attitude by boards of licensure in recognizing that no one type of internship possesses all the virtues desired.

FEMALE GENITAL HYPOPLASIA AND PREGNANCY

To the Editor—A woman aged 25 has been married six years and has had no pregnancies. She is desirous of becoming pregnant. Menstruation began at 14 but has never been regular since its onset. She has gone without a period for as long as a year. Her last menstrual flow was the third week in February previous to that it occurred in December 1936. Two weeks before onset she complains of severe cramping in the lower right quadrant. The breasts are rather large and pendulous and do not contain any masses. There is slight tenderness over the lower right quadrant of the abdomen. The cervix is smooth and small and there is a very slight erosion. The uterus is of infantile type anteverted and freely movable. The right ovary is twice the normal size slightly tender and freely movable. The left ovary is normal. The thyroid is normal. In 1934 she was given intravenously antuitrin S 0.04 cc daily for five days and one theelin capsule three times a day. This treatment was followed only two months. Since she came under my care I have given her for three months follutein 1 cc intramuscularly three times a week for two weeks followed by intramuscular theelin in oil 1 cc five times a week the third week in the month with a week of rest. During the third week she also takes two hormone tablets three times a day. She has not as yet had a menstrual period. I am interested in establishing a menstrual cycle with a later possibility of pregnancy. I would appreciate a suggestion of a plan of treatment to establish a cycle. MD Texas.

ANSWER—This patient's fundamental trouble is undoubtedly a female genital hypoplasia dating from puberty, and the results now show themselves in the form of functional derangements—evident disturbances of menstruation, and probably also a considerable degree of infertility. It is doubtful whether much can be done in such cases at the age of 25, since by that time the growth impulse and the developmental urge have been lost.

Within certain limits it is a rational procedure to use endocrine preparations as a remedy for amenorrhea and oligomenorrhea. In this particular case such treatment seems to have been unavailing.

The first step in the management of the case should be a complete examination with reference to medical and endocrinologic factors. Not uncommonly one finds a thyroid deficiency, even though the patient presents none of the classic signs of myxedema. For that reason repeated determinations of the basal metabolic rate are indicated.

As a last resort one might try light irradiation of the ovaries, a procedure the technic and results of which are described by Jarcho (*Gynecological Roentgenology*, 1931).

ALUMINUM HYDROXIDE AND KAOLIN ENEMA

To the Editor—Will you please clarify the article by Drs Ejerly and Brenhaus in *THE JOURNAL* July 17 1937 on these points: 1 The relative proportions or amounts of aluminum hydroxide and kaolin in 3 ounces of water for an enema. 2 The technic of rectal administration of this thick suspension. L L CORCORAN, MD, Rock Rapids, Iowa.

ANSWER—The preparation is a pure colloidal suspension of 3 per cent aluminum hydroxide and 15 per cent of kaolin. This mixture is used with an equal amount of warm distilled water. No difficulty is experienced in injecting this and a small rectal tube or rubber catheter is used for the administration.

BREATH SOUNDS OVER ABDOMEN

To the Editor—What is the origin of breath sounds easily heard with a stethoscope over the abdomen in a patient dying from hemorrhage? MD New York.

ANSWER—Breath sounds may be heard with the stethoscope over the abdomen in many normal healthy persons when the subject of the investigation indulges in forced breathing with the mouth open. It is assumed that the phenomenon is produced by the transmission of tracheal sounds along the vertebral column into the abdomen, although there is no proof to substantiate this assumption. A patient dying from hemorrhage is usually gasping for breath. That is to say he is indulging in forced breathing with mouth open. There appears to be no other reason why the breath sounds may be heard over the abdomen in such a patient.

and that other factors than type of internship should be considered in determining a man's fitness for examination and registration

The rigid exclusion from the licensing examinations of applicants who have not had a rotating internship will in the long run deprive the state of some of the best medical talent that would otherwise have been attracted to it. The reasons for this statement are as follows. It is my belief that medical students prefer teaching hospitals for internships, as a rule. They will seek such internships regardless of whether or not they are rotating in character. This means that in general the teaching hospitals have the pick of the graduating classes and they naturally take the best men. Since most of the teaching hospitals are straight service hospitals, it follows that on the whole the best men presenting themselves for licensure in any one year will be those who have had straight service internships.

DISCUSSION

DR FREDERIC A. WASHBURN, Boston. A study of the medical licensure statistics published in *THE JOURNAL* April 24 1937, shows that, in nineteen states, medical licensing boards require that a candidate should have an internship experience before they will examine him for licensure. In some states which require an internship the position that a rotating service be required has been taken by their boards of registration. In New Jersey the law reads that the candidate must have served at least one year in a hospital approved by the board. The other sixteen states which require an internship have as a rule in their laws a clause similar to that of the New Jersey law. The remaining twenty-nine states make no internship requirements of their candidates for licensure. I am not sure how many states now make the requirement of a rotating internship, but I have been told that the number is eight. That no man is fit to practice medicine who has not intern experience in most of its branches is not in my opinion a sound position. How did it happen that the states which demand a rotating service came to take this stand? I fear that the Council on Medical Education and Hospitals is not blameless. The standards of the Council are high. It has a staff of five engaged in inspecting hospitals approved for intern training. It is doing a remarkably good job in this field. Boards of registration in medicine may well consider that the hospitals which it approves meet all necessary requirements for the training of interns. The teaching hospital with the straight service gets the pick of intern material and gives a training far superior to the one year rotating service of the small hospital, yet several of the most important states in the Union choose the poorer man with the poorer training. The result over a period of time is bound to be a mediocre medical profession in those states. These states are forcing on their own young men who wish to study medicine and desire to settle in their native states the acceptance of inferior hospital training. Those hospitals which feel they must have rotating services should make them two years long at least. The one year service with three or four shifts is bad for the intern and worse for the hospital. Is it possible that these states have in mind forcing the great teaching hospitals to adopt rotating services? I believe that with further study of the subject they will perceive their error and the damage they are doing to their own states and will soon modify their requirements.

DR IRVIN D. METZGER, Pittsburgh. We have had resurrected today a problem which most of us thought was settled twenty years ago—that of the type of internship best suited to medical graduates. The legal regulations in a score or more states which require internship as a fifth year of medical education and the recommendations of the most discerning evaluating agencies prove conclusively that a rotating type of service is the only one that assures safe and competent general practitioners. Only such qualified persons are of legal concern to state boards. Many of us contended twenty years ago and have had no reason as yet to change our minds that an apprentice type of hospital training in which the recent graduate has had a carefully supervised service in each department of medicine in a minimum of one year's time is the ideal one whether he expects to enter general practice or pursue further studies looking toward a specialty. The ability to survey the needs of any

patient and the ability to determine the methods of meeting such needs can be done best by one who has the broader view in medicine and who has no biased trends in any one direction. A narrowed field of preparation induces a narrowed clinical conception of any case. In the questionnaires sent out by the reader, he was obviously unfair. He sought replies only from the teaching hospitals, and those, with one exception, were located in states in which no internship is legally required. The writer also was unfair in comparing the exceptional small hospital that gives a rotational type of service with the eminent teaching hospital that gives an elective service. A better comparison would have been made by considering the many larger and well organized hospitals that have followed the rotational services for years and which have consistently shown no desire to change. The writer also intimates that states which adhere to the rotational type of service ere long would be sure to decline in the efficiency of its practitioners of medicine. The state I have the honor of representing initiated internship as a legal requirement for the fifth year of medicine in 1914. My experience on the board throughout practically all this time has failed to observe any complaint against the rotational service, either from medical faculty or from individual practitioner. Internship aims to make amends for the weakness developed in medical practice when scientific passion swept through our profession some years ago and which shifted toward scientific culture the emphasis formerly placed on the art of medicine. When preceptorships of olden days were eliminated and the prospective physician was shunted from the high school to the college of science and thence into the medical school before he sensed the meaning of the profession, we inevitably acquired in students many professional misfits. Those days are gone, and let them be gone because of other serious weaknesses. However, we need, by the establishment of a proving period before full acceptance to the study of medicine, some such, perhaps, as the probation period now in vogue in schools of nursing to sensitize the longing neophyte early to the significance of the medical profession. At the end of his medical studies a complete apprenticeship internship in every department of medicine will help to establish more fully the sense of responsibility that is so needful in its practice. By some such procedure we may recapture this vital essence known as the art in medicine and may restore to practice even greater geniuses than the old family doctor.

DR HAROLD RYFINS, Albany, N. Y. I would draw your attention to the fallacy of Dr Metzger's remarks with reference to the training of engineers. Medicine is not engineering. Any analogies as to the proper training of engineers does not carry over into the field of medicine. He speaks about training the honor man of every class of engineers throughout the country, perhaps 1 per cent of the young engineers. If you carry that over into medicine and take the top man which would be about eighty medical men in the country, it really doesn't make any difference what training you give them those men will train themselves. What are you going to do about the other 99 per cent? The internship is potentially the most important and actually, the weakest link in medical education. It is potentially the most important point because it is at that time the young man can really begin to cash in on his four years of rather academic training. It is actually the weakest point because we have relatively, at least, neglected the educational factors of the internship. In the teaching hospitals, by and large, the educational facilities obtained during the internship years are very good. In the average hospital and, certainly, in the smaller hospitals for the most part, they are very bad. The young man is allowed to take a great deal of responsibility that he isn't trained to take, or else he imitates the bad practice of men who have not had the proper kind of training. It may be that he gets a sense of responsibility and thinks that he can do things but, as a matter of fact, he can either not do them well or not at all. Internship is probably essentially a part of the educational program of the student. If that is true it should be under the medical schools. The medical schools have the responsibility and the facilities for carrying out the responsibility for training the undergraduate medical students. They are the only people that have it. Sooner or later all the schools will have to take over the responsibility of the fifth year intern.

training and I hope they will not do it in any one set way. I hope some schools will have a rotating service and others will have mixed service, some will have one year services and others will have two year services, but at least it will be on an educational basis under the auspices of persons who are competent to run an educational program. I do not believe it advisable for the state to take on the guidance of the internship year at all. At present something like 97 per cent of our graduates voluntarily take internships, and I have never found a regulation which affects less than 10 per cent of any of the people affected is a very valuable one. There are certain exceptions. If you do decide that you really must require an internship of every one, it is a serious thing for any state body to set up fixed requirements. Having served as a member of a state body for fifteen years, I want to be recorded as saying that I know of no state educational organization or no state licensing body which has the money or the men or the facilities to speak authoritatively at all about the quality of internships in the hospitals throughout the country. The American Medical Association has five men working on it. They have done as good a job as can be done under the circumstances, but those acquainted with it including members of the Council, are aware that it is not nearly as good a job as ought to be done. There are many hospitals which are approved which should not be approved. They are constantly being visited and revisited. They should have a larger staff of inspectors to do the job properly. How is any one state board, with perhaps one inspector, going to take on itself the classification of internships throughout the United States? It is a preposterous assumption of power and it is a purely paper matter.

DR WILLIAM J. PEPPER Philadelphia. The lack of liberality of the Pennsylvania board is one of my greatest tribulations. Our students want a two year rotating service. I approve of a rotating service two years in length. There are very few of them in the state. Our boys, then, often want to go outside the state. If one says he wants to go to some other hospital outside the state they say 'Well, that is beyond our ken. We are not able to inspect it and we don't know, if you go there whether we will examine you. They scare the boy into taking an internship in Pennsylvania and then he has to take a one year rotating service.

DR E. M. MACFARLANE Iowa City. Coming from a teaching institution I have some definite notions. I agree with the thesis presented by Dr. Smith that we cannot be limited to the one type that both types of internship are valuable. I also agree with Dr. Pepper. We are hoping to establish in our institution a two year rotating service. I want to take exception as Dr. Pepper did to Pennsylvania. A man who graduated from our institution the second man in a class of nineteen and had a year's rotating internship in one of the leading teaching hospitals in the country, a year's straight internship in our own teaching hospital then one or two years in a tuberculosis hospital in Connecticut and two years in a tuberculosis hospital in Illinois and is now in a tuberculosis institution in Pennsylvania and cannot get reciprocity because he had only four weeks of obstetrics because he didn't learn how to run an x-ray machine, and because he can't get a certification showing just how many cases he had through this type of training yet he is a leading surgeon and is recognized over the country. I agree that we cannot be putting state barriers up.

DR A. S. BEGG Boston. I am a dean and while we have to skirmish around and find places for interns the question about what should be done in the states is beyond my ken. I agree that if we have a rotating internship it should probably be of two years duration. I am also of the opinion that there are many good straight services where a man gets excellent training in services which are not on his list. At the Boston City Hospital for example the two year internship in medicine allows the man, by consultation and otherwise to see a good deal of surgery, a good deal of pediatrics and a good deal of contagious diseases but yet it is a straight service. It has a lot of things to recommend it. I think the question of settling this matter by the state should be made as easy a modification as possible because we certainly know there are well trained

men from some of these teaching hospitals that ought to be permitted to practice medicine in all the states of the Union.

DR STANLEY H. OSBORN, Hartford, Conn. You cannot train a specialist to do general practice work, and you cannot train a general practitioner to do specialty work. What we need is both of these groups. I am strongly in favor of both for the benefit of the people on whom we are practicing.

DR ROBERT U. PATTERSON, Oklahoma City. Oklahoma is one of the states mentioned which require an internship before a license to practice is given. In addition, we have in Oklahoma a scarcity of practicing physicians. About 54 per cent of the graduates of the University of Oklahoma, in medicine, return to their own states to practice. That being the case two years ago we raised the rotation internship from twelve months to twenty-four months. I am in favor of straight internships as well as rotating internships. In Oklahoma we need the rotating internship. Our men are not able to get the training in Oklahoma except in a relatively few hospitals. We advise them to go to teaching hospitals, if it is possible but of course there are not enough teaching hospitals by any means to meet the demand. If a hospital is approved, we take it as evidence that it has a proper staff, a well organized staff and will take an interest in the interns when they are entrusted to its supervision, and a man who gets an internship whether it is rotating or straight, in an approved hospital will come out with the information which will make him safe to let loose on society. I am in favor of all kinds of internships but for Oklahoma I think the men who are going to practice there should have two years, at least, and that is our present position.

DR WINFORD H. SMITH, Baltimore. My remarks were not solely in favor of the nonrotating type of internship. The whole burden of proof was to get recognition of some other type than the rotating type. I believe these other types are entitled to recognition. Dr. Metzger said I was unfair in comparing the straight internship in the large teaching hospital with the small hospital, as I did. I grant it is unfair, but that is the requirement which is set up in some of the states. For that reason I picked it out because I repeat, to me at least it is more or less absurd to compare a rotating internship of one year in a hospital with a daily average of fifty patients with a straight service in a well organized teaching or nonteaching hospital with a sufficient number of beds and sufficient opportunities of an educational character to make that service valuable. My plea is do not limit your recognition to those who have had only a rotating type of internship. I recognize that there is merit in a rotating internship. I also maintain that there is distinct merit in other types, including the straight internship.

DR I. D. METZGER Pittsburgh. Nobody regrets more than I that we are tied down by law to a strict form of rotational type of internship. I wish we were given discretionary powers in many things with respect to the medical act so that we could do the thing we feel we ought to do. The law was amended two years ago to the effect that when a person has been out seven or more years the board may accept an equivalent for internship. We are very glad to accept straight internship when that is the case. I do not, however state that we ought to have a straight internship and encourage that. I think we still ought to have the rotational type for at least one year, perhaps not so exacting as we require for Pennsylvania.

American Students in Italian Medical Schools

WILLIAM C. MACFARLANE New York. As the majority of American medical schools require more than the legal minimum requirement of preliminary education, the Italian authorities have agreed to require at least three years of preliminary education for entrance to Italian medical schools. In addition, applicants whose records are otherwise satisfactory are required to demonstrate by examination that they understand the Italian language.

Any American student who desires to apply for admission to an Italian medical school is now referred by the Italian consul in his locality to the Royal Italian Consulate in New York City. He is required to submit a certified copy of his previous academic record. The record is evaluated from the

standpoint of the character of courses completed, general scholastic average, science average and percentile score on the medical aptitude test. The Italian authorities have given friendly cooperation in every way.

The majority of Americans now studying medicine in Italy are matriculated at the University of Bologna. The greatest number were matriculated in 1933-1934 and since then the number has decreased yearly because of the strict control of the commission established at the royal Italian consulate at New York, which has the duty of examining the credentials presented by candidates for admission. Arrangements were made to provide for obligatory posts for internships for American students at the institutes and hospitals, starting with the year 1936-1937, and sixty-five places have been provided.

Foreign Medical Students

DR C. B. PINKHAM, Sacramento, Calif. Postbellum problems of growing importance to this congress have challenged the standards of medical education and licensure in this country. During the past few years a rapid change in both medical education and licensure has come about in foreign countries. The seriousness of the situation has caused growing concern as to the future of the heretofore high standards, both ethical and economic, of medical practice in the United States. When it was learned several years ago that a large number of our younger men and women had left the United States, intent on studying medicine in some foreign school, many of the medical examining boards in this country seemed indifferent to the serious problem which would be faced when as graduates, this group would return to the United States and materially increase the normal influx of foreign medical school graduates intent on qualifying for a license to practice medicine. We comment on the frequency with which graduates of German medical schools file a large document printed in Latin on thin paper and showing (lower margin) what purports to be the seal of the institution. This "seal" is also printed thereon. Such a document purports to be a copy of the applicant's original medical diploma. When questioned, he explains that his original medical diploma is kept in the archives of the university and that a graduate may secure several printed "copies" for use. We ponder as to how many alleged medical school graduates are foisted on the public via a local print shop. During twenty-five years' continuous service as a member and the executive officer of the California Board of Medical Examiners, I have uncovered many fraudulent credentials, including purported medical diplomas.

The majority of the medical examining boards comprising this federation are now thoroughly awakened to the seriousness of the problem presented by both the foreign medical student and the foreign medical school graduate. Many states have refused to license applicants who hold foreign medical credentials. Others, including California, have amended the law governing medical licensure so as to conform with the resolution adopted by the Federation of State Medical Boards at its 1933 session and by the House of Delegates of the American Medical Association at its May 1936 meeting in Kansas City. The problems involved demand that not only medical examining boards but every organization interested in medicine guard against the threatened destruction of the high standards of medical education licensure and practice, which for so many years we have struggled to uphold.

DISCUSSION

DR WILBURT C. DAVISON, Durham, N. C. The clinical teaching of an American medical school is far superior to that of practically all the foreign medical schools I have seen, and I have seen most of them. For that reason there is good training there. If the American Medical Association or the Federation of State Medical Boards, and so on set up rules with regard to excluding certain students we get into diplomatic difficulties but the individual medical schools can do this, if they decide to admit or not to admit these students into their third or fourth year there will not be many of them admitted which I think is desirable. In Dr Pinkham's paper one requirement has been set up, namely, with regard to coming into American hospitals as interns. That I don't think

is worth the paper it is written on. There are 6,700 hospitals in this country crying for interns, and they will take almost anything that can walk. I have hundreds of letters on my own desk asking for any kind of intern, it doesn't make any difference whether it is good, bad or indifferent. Mr. MacTavish's figures showed from twenty-one to thirty-seven students a year are going to Italian schools alone. It is really the equivalent of an additional American medical school. Most of those students are city students. Figures show that 80 per cent or more of the city students go back to practice in the city, a field that is overcrowded. In North Carolina there are counties with one physician to 3,500 of population, in South Carolina there is one physician for 4,500 of population. And though the profession is crowded in New York, Chicago and Philadelphia, in the rural districts additional doctors are needed. Why make the present amount of maldistribution worse by increasing the city students, who are largely the ones who go to the Italian schools? An exception should be made for those who are outstanding in their field and have practiced ten years in foreign countries and come over to this country.

DR JAMES N. BAKER, Montgomery, Ala. Two underlying causes which have precipitated this problem are (a) an ambition on the part of American parents to have their offspring trained somewhere, somehow, for professional careers and (b) the disturbing political unrest throughout Europe, which has been and is now forcing many professionally trained persons to seek greater security elsewhere. Professor MacTavish's paper deals with a culling process applied by one state to a particular group headed for the medical schools of Italy and with 72 per cent of failures, over a five year period, to meet the qualifications considered by him to constitute a fair test. One wonders about the outcome had similar tests been applied to the entire group of 1,648 enrolled in foreign faculties from the United States in 1936-1937. True enough, there has been some decrease in 1933-1934 there were 1,905, in 1934-1935 there were 1,944 and in 1935-1936 there were 1,637, with 333 completing their courses in this year. California in an effort to comply with a resolution passed by the 1936 House of Delegates of the American Medical Association, has clamped down, no doubt other states, as they encounter present difficulties of evaluating the foreign graduate, will be forced to resort to various devices and to varying degrees of drasticity. Necessarily there will likely follow a conglomerate, incoherent and confusing medley of state regulations bearing on the foreign graduate. Such an unhappy state of affairs already exists regarding medical licensure in general. Might it not be possible at this time and before greater obfuscation arises to attempt to envisage this problem as one national in scope and have the remedy or regulations to be applied broad based on such a concept?

DR I. D. METZGER, Pittsburgh. There is not a state board in the United States that does not constantly face this proposition. We in Pennsylvania are right near the gateway into which these people come, and it has been necessary from the very beginning to watch carefully the credentials of them all. We don't require that they be licensed but they must have certification that they may be licensed. Internship should be in America, preferably within one of our own hospitals, in which we can check up on the type of work the candidate is doing. This internship can be granted only after the credentials have been approved by the board, so that the person may eventually be licensed to practice in the state. That is where this weakness comes in the internship business. If the credentials are inadequate, the person may not enter a hospital for internship in Pennsylvania. Examination means written examination and bedside examination or practical examination of each one of these candidates.

DR J. C. SIMPSON, Montreal. Will the Federation, in considering this matter, please take into consideration the fact of the very close linking of the Canadian schools with those in the United States taking cognizance of the fact that the same assessing agencies, the same inspection agencies cover education in the two countries and perhaps try to differentiate to some degree, at any rate between the Canadian schools and those in Europe.

DR H M PLATTER, Columbus, Ohio In Ohio we have gone as far as we can, without additional legislation, to meet this vexatious problem Our attorney general tells us that we cannot enact resolutions which are legal and binding beyond the purview of a statute, but we can elaborate on the statute and tell how an individual from a foreign country may meet and submit credentials that are the equivalent of what we demand here

DR L J KOSMINSKY, Texarkana, Ark In Arkansas we have two boards, the regular and the eclectic I represent the regular The regular, by resolution, since 1928 has required a man to be a citizen of the United States to take the board examination

DR THOMAS J CROWE, Dallas, Texas Texas is a border state, and it is easy to cross the Rio Grande River Sometimes one can wade it in most places I believe we have enough of certain types of foreign graduates in the United States, and I don't think we should prepare the way for more Mexico won't allow us in there at all, and I don't see why we should take Mexican graduates

Book Notices

The Rehabilitation of Speech A Textbook of Diagnostic and Corrective Procedures By Robert West Ph.D. Professor of Speech Pathology, University of Wisconsin; Lou Kennedy Ph.D. Associate Professor of Speech, Brooklyn College, New York; and Anna Carr M.A. Clinical Adviser in Speech, State Teachers College, Milwaukee, Wisconsin. Cloth Price \$4. Pp. 475 with 28 illustrations. New York & London: Harper & Brothers, 1937.

The repetitional features of most books on the subject of speech disorders causes them to be placed in the category of academic interest for only a brief time. This book is different, because the arrangement of material is original and tends to meet in a practical way the specific needs of an ever widening specialty. It covers the field of speech disorders in a comprehensive manner. The material is divided into five main parts. Part one is a creditable effort. Under the general heading of diagnostic procedures, the neurophysiologic mechanism for speech is briefly covered so that the reader is technically prepared for both normal and abnormal speech development. Then follow those speech disorders which fall into the category of abnormal psychology, psychopathology or psychiatry, that is those which have no organic or structural basis. Although the authors consider stuttering a psychogenic disorder, they also state that, "while psychogenic disorders are undoubtedly functional in nature, they are nevertheless more prevalent among children showing poor physiological and neurological stability." They point out the fact, under hereditary background that "the condition underlying the stuttering is transmitted from parent to offspring by biological heredity." They further point out that the stutterer has a special makeup, "a type of constitution that, though rugged, is not suited to the exigencies of social life," and that a secondary phase of stuttering is the reaction of the patient toward his stuttering speech, which ultimately warps his whole personality and leads to the development of a definite neurosis—an anxiety neurosis. The chapters which follow deal with dyslalias caused by mouth deformities such as cleft lip, cleft palate and dental anomalies. Under "Rhinolalia Caused by Nasal Obstruction" the authors advocate the use of Dr. Russell's term, "cul-de-sac resonance." Since the quality of tone known as nasality is the result of resonance in a cul-de-sac resonator, it would be better to refer to this quality as "cul-de-sac resonance" than as "nasal resonance." This is a practical suggestion which should be appreciated by vocal and speech teachers. Another chapter deals with vocal defects caused by pharyngeal and laryngeal deformities. It tells briefly, both etiologically and therapeutically, about many dysphonias of importance to the speech pathologist. There is a clear and informative chapter on neuropathologies of speech spastics, and the speech involvement of the feeble-minded is also briefly touched on. Dyslalias caused by deficiencies of hearing are extensively treated so that the student gets a concise working knowledge of the entire field of hearing defects, and the authors conclude part one with a chapter on case study and diagnosis, which should prove of practical value to speech practitioners.

Part two is given over to remedial procedures for older children and adults. The authors outline types of speech clinics and the characteristics which the clinician should possess. There are the usual general exercises for the tongue, lips and velum, and several chapters describing the articulatory adjustments for special articulatory defects. There is also a discussion on the therapy of the stutterer. Various phases of remedial procedures are given, but as in most cases—since the subject is of such an intangible and personal nature—they still leave much to be desired. The remainder is devoted to therapy for cleft palate speech, rhinolalia, vocal disturbances, spastic speech and speech defects of the feeble-minded. Part three gives remedial procedures in the form of exercises and drills for cases of omissions and substitutions of sound units in the speech of children. Part four is a treatise on foreign language influence. The factors in the retention of a foreign accent are pointed out, and the usual measures are outlined to counteract the various oral inaccuracies. Part five deals with speech reading, that is, the teaching of oral speech to the deaf. The

few exercises for lip reading are given in phonetic transcriptions to secure accurate symbolization of sounds.

Following these five major parts, the book has an appendix containing a number of practical features which should prove of value to the teacher and student of speech. There are, in addition, clear and instructive illustrations throughout the book. The twelve plates showing the position of the articulators, however, would perhaps be of more interest to the reader if they were in color. In black and white they are drab and detract from the appearance of the book. The authors deserve special commendation for excluding controversial matters. By so doing, the distracting controversy which has long centered around handedness in connection with stuttering is eliminated. Therapeutic measures, however, should have had more elaboration, and issue should be taken with the statement made on page 64 that "the adult stutterer who has developed the psychoneurotic aspect of dysphemia is likely to continue to stutter the rest of his life." This does not coincide with the experience of others in this special field. Here and there a little more detail in less technical terminology would have proved more helpful to the student who has not received special speech training. Also fewer phonetic symbols should have been employed. While phonetic symbols have their place in a book such as this, readers unfamiliar with them will find their excessive use confusing rather than clarifying. Naturally, any work of this type is rather heavy, but this book seems unnecessarily so as though in their desire to be technical and scientific the authors overcompensated. This, however, does not alter the fact that as a textbook of diagnosis and corrective procedures "The Rehabilitation of Speech" will undoubtedly fill a long-felt need.

Diseases of the Skin A Manual for Students and Practitioners. By the late Robert W. MacKenna M.A. M.D. Ch.B. Fourth edition revised and enlarged by Robert W. B. MacKenna M.A. M.D. M.R.C.I. Honorary Dermatologist, Royal Southern Hospital, Liverpool. Cloth Price \$3. Pp. 507 with 234 illustrations. Baltimore: William Wood & Company, 1937.

The arrangement of the material is in twenty-six chapters, the scheme in the main etiologic beginning with anatomy, physiology, examination and treatment followed by descriptions of coccic tuberculous protozoal fungous, parasitic and virus diseases of the skin and terminating with discussions of diseases especially affecting the hair, fat glands and sweat glands, pigmentary anomalies, "tumours" and finally diseases of the nails. The type is large and easy to read. It is written for the medical student and general practitioner, its four paragraphs, less than one page on pathology will not help a candidate for the American specialty examinations. All common dermatoses are described satisfactorily and in a practical manner. Sabouraud is followed in the consideration of streptococcal dermatoses, under the title of "Subacute and Chronic Forms of Impetigo" as has recently been stressed by James H. Mitchell in this country. Tuberculosis is well presented, in part, of course, because it is common in Great Britain. Schamberg's disease, the primary skin complex, the usually negative tuberculin reaction in sarcoid, the salt free diet and treatment by physiotherapeutic agents are all appropriately discussed. The photographs are good but not excellent—the author would learn from George Miller Mackee and Howard Fox—but the colored plates should be the envy of American writers, who cannot get publishers to pay for them. Neither Sutton's nor Ormsby's textbook is comparably embellished. The style of positive statement, direct and brief, is an advantage to the beginner. Some sentences are intentionally bald and so stick in the memory concerning the Wassermann test. "The reaction is not a specific test for syphilis, a fact profitably retained." As J. Girdner Hopkins recently said, nobody knows what the Wassermann reaction is or what causes it. Treatment of syphilis by courses with rest periods characteristically not American will antagonize any one familiar with the conclusions of the Cooperative Clinical Group. References to recent journal articles are few but selected. They are almost all in English and the majority are British. Altogether, the book is a sound compilation of basic dermatology well written, well illustrated, no more debatable as to its content than other works and, as it represents a particular school of thought, next to MacKenna's pretentious work it is the best of the British textbooks.

The Microtommist's Vade Mecum (Bolles Lee) A Handbook of the Methods of Animal and Plant Microscopic Anatomy Edited by J Bronte Gatenby M A Ph D BA Professor of Zoology and Comparative Anatomy Trinity College Dublin and Theophilus S Painter A B A M Ph D Professor of Zoology Texas University Austin Texas and others Tenth edition Cloth Price \$9 Pp 784 with 11 illustrations Philadelphia P Blakiston's Son & Co Inc 1937

For fifty years Bolles Lee's book has been widely used in histologic and embryologic laboratories. It continues to be a standard and convenient reference work for the research laboratory. The present editors have tried to widen its scope by adding a brief outline of technical procedures, but the encyclopedic character of the work makes it unsuitable for beginners especially as there are several good elementary manuals available. Bolles Lee personally tested every method he thought worth including in his book. Dr Gatenby finds this impracticable at the present time, so many new methods have been accepted on the authority of those who have described them. On the other hand he has added critical discussions of certain cytologic problems in fixation and staining which should clarify the situation. There are still many biologists who believe that staining methods have the specificity of qualitative chemical tests. A careful reading of these discussions should make obvious the inadequacy of the technical procedures such misguided workers have used. The size of the book was rigidly kept down in the first seven editions of Lee. In this edition the book is 50 per cent larger than in the seventh. Ninety-eight pages on botanic methods (by D G Gatcheside) have been added, as well as sixteen pages on vital staining (R J Ludford). A new chapter on chromosome methods has been written (T S Painter). The sections on general and special techniques have been amplified in many ways. The new treatment of fatty substances (by W W Kay and R Whitehead) is especially commendable. Naturally there are regrettable omissions. There is no mention of the newer silver on-the-slide methods which have made it possible to obtain impregnations in well fixed material free from the numerous artefacts of the silver in the block procedures. The work continues to be well edited and printed, now it has a water and vermin proof binding to boot.

Handbuch der Artefakte Morphologische und funktionelle Simulationen und Dissimulationen Herausgegeben von Dr med Julius Mayr o Uni versitätsprofessor und Direktor der Dermatologischen Klinik und Poliklinik der Universität Münster (Westf) et al Paper Price 22 marks Pp 470 with 135 illustrations Jena Gustav Fischer 1937

The authors present a thorough analysis of the various types of malingering (simulation and dissimulation) so often resorted to for purposes of gain by individuals of normal psychic make up and by patients of psychopathic constitution. The work is divided into eleven sections, with a number of subheadings. Hermann Stefan discusses simulation and dissimulation in psychiatry and neurology. A general discussion of this subject matter is presented and is followed by the description of the psychologic and psychopathic substrata for self-inflicted wounds and self mutilation. Case histories of individuals of sound mind, of congenital inferiority and of patients suffering from the symptom complex of epilepsy, schizophrenia and hysterical habitus augment the text. A thorough index and a summary of the material presented concludes the chapter. The second division of the work is contributed by Julius Mayr. Forty-one well executed photographic illustrations embellish the text. It deals particularly with skin lesions produced by malingerers. Illuminating case histories are recorded. The methods resorted to by patients to produce various pathologic states their morphology, the differential diagnosis and the treatment are described. The author calls particular attention to simulations resorted to by those in military service. Venereal disease artificially produced is described. A thorough bibliography is appended. The other divisions of the work describing simulations of diseases in the region of the neck, nose and throat (Wilhelm Berger), simulation of diseases and functional aberrations of the eye (Oswald Marchesani) and those of internal diseases (E W Baader) are written in the same engaging manner as the preceding chapters. Simulation of drunkenness, lead poisoning, silicosis, diabetes, disease of the gastro intestinal tract and respiratory diseases are discussed. Chapter 6 (Carl Ludwig Gross) is of particular interest to the surgeon. Here are described methods used by malingerers to produce a large

variety of conditions, including artificial inguinal hernia, prolapse of the rectum, rectal fistula, injuries to the sex organs, diseases of the genito-urinary apparatus, artificial tumors, artificially produced subcutaneous emphysema, diseases of the joints, mutilation and injuries of portions of the extremities, artificially produced inflammations and phlegmons, introduction of foreign bodies into the gastro-intestinal tract and other portions of the body, production of ulceration, gunshot wounds, artificial swellings and simulation of diseases of the stomach and lungs. All these make interesting and informative reading. F Siegert contributes an excellent chapter on simulations and dissimulations in gynecology. Otto Ullrich is the author of artificial clinical manifestations in childhood (chapter 8). The work concludes with the medicolegal aspects of the questions discussed, supplemented by an author's index and a good general index. The work can be highly recommended to the general practitioner, specialist and surgeon and particularly to those who are engaged in work which may require the rendering of opinions before industrial boards, insurance companies and in courts of justice, besides being informative from the general educational point of view and affording food for reflection on the ingenuity of the human mind to gain an end.

Lipogenesis in the Animal Body with Special Reference to the Physiology of the Goose By Francis G Benedict Director Nutrition Laboratory Carnegie Institution of Washington and Robert C Lee Carnegie Institution of Washington Publication No 489 Paper Pp 232 with 30 illustrations Washington D C Carnegie Institution of Washington 1937

This monograph presents the gathered ends of twenty-three years of sporadic investigation at the Carnegie Nutrition Laboratory on the metabolism of the goose, particularly with reference to the problem of fat formation. The collected work represents a mountain of labor and investment and the outcome appears to be a not very large body of new fact. The only new conclusion of fundamental significance, which is unfortunately supported by relatively meager data, seems to be that, contrary to expectation, one finds no difference in the calorific equivalent of oxygen by comparison of direct and indirect calorimetry, regardless of whether carbohydrate is being burned or being laid down as fat. This statement is in reality a denial of the laws of thermodynamics and is inherently improbable. It is supported by a scanty five observations which vary by 5 per cent among themselves, whereas the expected difference in the particular experiments is just about this amount. No statistical treatment is given but a rough statistical calculation shows that the authors are absolutely unjustified in their deduction. The final conclusion of the authors of the monograph may be quoted in their own surprising words. As a result of our experience with direct calorimetric measurements on geese during surfeit feeding of carbohydrate which showed essentially negative results so far as the presence of exothermic heat is concerned, we believe that any further direct calorimetric observations on animals would be unprofitable and their final sentence, "As a result of our experience with geese we would not recommend any further direct calorimetric measurements." As a private recommendation to the regulating body of the Carnegie Institution with regard to the program of the Nutrition Laboratory this may be a valid suggestion, but as a dictum for other investigators it is absurd. The deductions from the experiments presented in the monograph in reality throw out a sharp challenge to a new generation of biophysicists to improve existing techniques so that the applicability of the laws of thermochemistry to biologic systems carrying on such processes as fat synthesis can be adequately tested in more than five experiments and with a random error of less than the order of magnitude of the differences expected.

One suspects that the laws of thermodynamics cannot be dismissed as summarily as Benedict and Lee have dismissed them. It might be inferred by the reader that Benedict and Lee labored under the delusion that what was impossible with their skill and with the resources of the Carnegie Institution simply could not be done. One recalls the classic prediction of Müller that the velocity of the nerve impulse could never be measured ten years before Helmholtz performed the feat. Benedict and Lee have not said that the laws of thermodynamics will never be shown to apply fully in the living organism.

but they have advised against trying to establish such applicability. Especially since they have said in essence (p. 231) that in practice one should deny the applicability of thermodynamics to lipogenesis, these authors are open to strong censure for their uncritical attitude as regards their own experiments and reasoning.

After urging that all direct calorimetry on animals be abandoned, the authors grudgingly admit that such work on pathologic human beings might still be useful. How the latter can be worth while when the former is not is difficult to comprehend. The remark might be interpreted as a means of escape from criticizing the Russell Sage calorimeter work while insisting that all the animal work that could profitably be done is now complete. In certain other respects the book is worth while. The analysis of the effects of feeding and the influence of obesity on the total metabolism are valuable. The added proof that stored fat is not without effect in raising the total energy expenditure of the organism is important to medicine. The studies of heart rate and other general physiologic phenomena are contributions to comparative physiology.

Statistical Methods Applied to Experiments in Agriculture and Biology. By George W. Ennedore, Director of the Statistical Laboratory of Iowa State College Ames, Iowa. Cloth. Price \$3.75. Pp. 341 with illustrations. Ames, Iowa: Collegiate Press, Inc. 1937.

The proper understanding of statistical methods in biology and medicine appears extraordinarily difficult to most physicians. Hence investigations requiring a statistical presentation are often unsatisfactorily prepared, the problem is dodged, or the figures are merely supplied to a "statistical expert." The author of this volume believes that an advanced mathematical training for the use of the statistical method is not necessary. This book is therefore designed for an individual to study by himself. The material is divided into chapters on the various elements of the statistical method, namely, attributes, individual comparison, group comparison, short cuts, regression, correlation and analysis of variants. Each point is illustrated by examples of graduated difficulty. Although the material constitutes difficult reading for most physicians, the book has something definite to offer to those who have the time and interest to devote to unaccustomed studies.

Die Lungenerkrankung der Paprikaschäler. Von Dr. Franz v. Kovats, o. Professor, Vorstand der städt. Lungenfürsorgestelle in Szeged (Ungarn). Tom. VIII, Fasc. 1, Acta litterarum ac scientiarum reg. Universitatis Hung. Franciscus Josephinae, Sectio Medicorum, Boards. Price 4 marks. Pp. 92 with 35 illustrations. Budapest: Eggenbergersche Buchhandlung, Karl Renyi, Leipzig: Johann Ambrosius Barth, 1937.

The pulmonary diseases of paprika cutters exhibit a peculiar form previously unknown pathologically. The first case of a paprika cutter having a lung disease was observed for a period of six years without information being obtained that would lead to the discovery of the real cause or causes of the phenomena. The need for a comprehensive study led the author to a thorough investigation of the various factors involved in the disease. He has collected all available information on the known cases and investigated the accompanying circumstances. The relationship is shown among the various pathologic conditions. The dissertation starts with a discussion of the varieties of mold growing in paprika and the causes of illness of paprika cutters. The author believes that the disease is due to the development of a mold fungus accompanied by numerous spores. This is based on the finding of fungous infection in the lung. These spores cause catarrh of the air passages which in turn leads to acute forms such as bronchitis and exudative bronchiolitis. In a short time a subacute condition appears characterized by a treelike formation and changes of the costal pleura. It is stated that the chronic disease appears after about ten days. The end results consist in a spreading fibrosis and bronchiectasis. Symptomatology and diagnosis, illustrated by roentgenograms, are followed by a discussion of the pathologic conditions for about 200 individual cases. The various forms of the illness are described under the headings (1) acute, (2) subacute and (3) chronic. Acute conditions include bronchitis and peribronchitis, which cannot be differentiated by x-ray plates. Congestion of a catarrhal type and exhaustive bronchiolitis are considered next. Numerous plates illustrate the

various forms. It is stated as a general theory that the numerous manifestations of the chronic form can be seen only after an exposure of approximately ten years. The separate chapters that follow are on complications, differential diagnosis and prognosis. The book closes with two pages devoted to prophylaxis and therapy.

The Surgery of the Sympathetic Nervous System. By George L. Calet, CMG, DSO, FRCS, Consulting Surgeon, St. Bartholomew's Hospital, London, and J. Paterson Ross, MS, FRCS, Professor of Surgery, University of London. Second edition. Cloth. Price \$1.50. Pp. 191 with 50 illustrations. Baltimore: William Wood & Company, 1937.

That this little monograph on so specialized a subject should have met with a demand for a second edition within less than three and one-half years is ample evidence of its value to the medical profession. So enthusiastic a reception for a work of this type is surprising. The authors have adhered closely to their title. The clinical history of the diseases with which they deal finds little place here. The book presupposes a thorough knowledge of the conditions under discussion. The unformed will find little to aid them in diagnosing their cases. Differential diagnosis is not considered. The authors' sole concern in this direction is with selection of cases for operation from among those already recognized and classified. The discussion of the anatomy and physiology of the sympathetic nervous system is minimal, being restricted to that absolutely demanded by their discussion of surgical procedures. The discussion of the surgery of the sympathetic nervous system is sound and conservative with the possible exception of three minor sections dealing with the relief of dysmenorrhea and of vesical and renal pain, with which the authors seem to have had little or no experience. At least they cite none of their own experiences and uncritically accept a number of unduly enthusiastic reports from the literature. In this connection it is to be noted that the authors recommended that only cases of dysmenorrhea "of the spasmodic type" be submitted to sympathectomy and that "the operation should never be performed for the congestive type" without any indication as to how this differentiation is to be made. It is of interest that the authors have accepted completely Lewis's views as to the pathophysiology of Raynaud's disease. But in so doing they have ignored all evidence antagonistic to this view, even that present in their own observations reported in these pages. It is also noteworthy in connection with this uncritical attitude that their statement on page 113 relative to Raynaud's disease, that although sympathectomy does not result in a vasodilatation comparable to the normal state "the sympathectomy enables the vessel lumen to remain open when exposed to a degree of cold which was previously sufficient to close it," their own observations presented in figure 39, page 111, are to the effect that the degree of vasoconstriction, as indicated by surface temperature, was greater (not less) under identical conditions following the sympathectomy than it was before. The authors' attitude in general toward ganglionectomy in the treatment of Raynaud's disease of the upper extremities is favorable to a degree not compatible with the experience of other surgeons. In the main the book is sound. It is clearly and concisely written, the typography is excellent and the illustrations are good. There is a satisfactory index.

Verzögerte Knochenbruchheilung und Pseudarthrosenbildung ihre Ursachen und Behandlung. Von Prof. Dr. Georg Brandt, Vorstand der chirurgischen Klinik des städtischen Krankenhauses Mainz. Paper. Price 13.50 marks. Pp. 170 with 223 illustrations. Leipzig: Georg Thieme, 1937.

The author offers a concise but exhaustive presentation of the subject. The first chapter is devoted to the histologic course of normal bone healing and such variations of it as lead to the development of aberrations and deficiencies, the observation being based largely on Lexer's views on pseudarthrosis. The next chapter is devoted to the pathologic description. The author discusses the causes of nonunion from the constitutional and nutritional from the general as well as from the local point of view. There is nothing new offered in the chapters on the general causes. From the local point of view some interesting features are discussed, important mechanical dynamic factors particularly disturbance and imbalance of stresses are cited as predisposing factors or as causative agencies. Here an interesting feature is the discussion of the mutual influence

of the parallel forearm bones on the formation of transformation zones and pseudarthroses, the influence of the fibula on pseudarthrosis formation, and healing of the tibia. The chapter on treatment reviews the usual osteoplastic methods and adds a few less well known items. Of interest is the application of osteotomy on the neighbor bone in the treatment of pseudarthrosis of the forearm, the block action of the fibula, and the effect of the osteotomy of it on healing of the pseudarthrotic tibia. The last chapter is devoted to the description of casts and braces and supportive apparatus. The volume does not contain a great deal of new facts but is well written and concise. It should be of particular value to the general surgeon who is interested in reconstructive work on the bones.

The Practitioners Library of Medicine and Surgery Volume XII
Preventive Medicine and Hygiene Supervising Editor George Blumer M.D. David P. Smith Clinical Professor of Medicine Yale University School of Medicine Associate Editor Ira V. Hiscock M.A. C.P.H. Professor of Public Health Yale University School of Medicine Cloth Price \$10 Pp 993 with 45 illustrations New York & London D. Appleton Century Company Incorporated 1937

The twelfth volume of the Practitioners Library of Medicine and Surgery is a sound, composite textbook on preventive medicine and hygiene. Such a book is of the greatest importance in rural medical practice. After a discussion of periodic physical examination there are special chapters dealing with water, clothing, exercise and rest, excretions, sunshine, cleanliness and personal mental hygiene. The second portion of the book concerns preventive medicine as it applies to groups of human beings, the third section deals with community health, the fourth section covers the prevention of infectious diseases, as well as the diseases of the various systems of the human body. All the men selected to prepare various portions of this book are writers who have had special training and interest in the topics they discuss. The book is practical, authoritative and obviously a fundamental addition to this system of medicine and surgery.

Short Years *The Life and Letters of John Bruce MacCallum* M.D. 1876-1906 By Archibald Malloch Cloth Price \$3.50 Pp 343 with 15 illustrations Chicago Normand House 1938

John Bruce MacCallum, brother of Dr. W. G. MacCallum, was born June 8, 1876, and died in 1906—just 30 years of age. After studying at the University of Toronto and Johns Hopkins, he traveled to Germany for postgraduate study. He returned broken in health and much of the rest of his brief career was spent in search of recovery. He was in Denver as a teacher of anatomy and at the University of California, where he worked with Jacques Loeb. In 1905 he acquired a severe albuminuria which, associated with extensive chronic tuberculosis, resulted in his death. Dr. Archibald Malloch has written the biography of the man largely by the use of his letters and poems. For those who knew him and who knew the families of Osler, Malloch and MacCallum, this book will constitute a beautiful as well as a most interesting volume of memory and reminiscences.

Über sogenannte kosmische Rhythmen beim Menschen Von Professor Dr. B. de Rudder Direktor der Universitäts-Kinderklinik Frankfurt a. M. Paper Price 1.80 marks Pp 46 with 2 illustrations Leipzig Georg Thieme 1937

The author expounds the possible effect of cosmic influences on man. He does not mean occult phenomena but geophysical effects and considers this new field of study bioclimatic or meteorobiologic. Many influences of an extraterrestrial nature are mentioned as theoretical possibilities, but no actual correlations are given between them and variations in man. His proposed field is one in which Peterson has long worked (*The Patient and the Weather*) but the author is unacquainted with this work.

Poisoning the Public *Daily Contacts with Toxic Materials as Civilization Marches On* By Russell C. Erb Cloth Price \$2.15 Pp 219 Philadelphia Dorrance & Company 1937

The author of this book has tried to survey the field of toxicology as it relates to contact with poisonous substances in water, food and atmosphere in flora and fauna, in the household in industry and even in war, all this in a small volume intended for the public. Unfortunately the work is poorly organized and clumsily written. It contains many errors of fact,

judgment and interpretation too numerous for specific citation. It is likely chiefly to frighten the "daylights" out of the average layman, without giving him a sufficient background of accurate information. The layman should know the potential sources of intoxication and how to avoid them; he should be able intelligently to support legislation designed to remove many of the current menaces to health. But it will require a more adequate study than this to give him a reasonable understanding of this important subject.

A Meandering Hoosier By Hugh A. Cowing M.D. Cloth Price \$2.15 Pp 257 with 61 illustrations Muncie Indiana Scott Printing Company 1937

In this book Dr. Hugh A. Cowing has assembled his personal impressions of many interesting places which he has visited, some marvelous reproductions of photographs, and some miscellaneous poems developed in connection with his travels. Other physicians who have traveled the path that he has followed and who are interested in medical belles lettres will find the book interesting and entertaining.

Tenth Annual Report of the Missouri Workmen's Compensation Commission The Statistical Year of 1936 and Operating Year of 1937 Paper Pp 20 Jefferson City Missouri [n.d.]

The number of accidents in 1937 was 73,741, compared with 70,243 in 1936. The Missouri workmen's compensation law has been in operation since January 1927, and during the period from January 1927 to January 1937 729,209 cases were reported to the Commission on which \$24,710,961.99 was authorized in compensation and \$11,269,835.62 in medical aid—a total of \$35,980,797.61.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts *Accidental Injury Defined*—As the workman, in the course of his employment, was loading cartons of bread weighing from 35 to 40 pounds each, he turned suddenly to get a better hold on one carton and felt a sharp pain in his left side. It gave him a sickening feeling all over, especially in the stomach, and he was compelled to sit down for twenty or thirty minutes until the nausea passed away. He had bearing down pains thereafter and that night he discovered a hernia on the left side. In resisting his claim for compensation before the industrial commission of Utah, his employer's insurance carrier contended that, although the injury in question occurred suddenly, undesignedly and unexpectedly at a definite time and place, yet it could not be termed an accidental injury within the meaning of the workmen's compensation act unless there was present evidence of strain or overexertion, in the absence of some unforeseen or unusual happening, and that there was no evidence in the present case of strain or overexertion. The industrial commission, however, awarded compensation to the workman and an appeal was taken to the Supreme Court of Utah.

The word "accident" as used in the workman's compensation act said the court, is not limited to any arbitrary, legal, technical or contractual meaning nor to things external to the person injured, as falling bodies, explosions, or breaking of equipment which in turn injures the workman. It includes also the injury to the workman himself. The injury is an accident when it results, not from the wear and tear on the body of the workman incident to long continued effort but when it occurs unexpectedly as a result of the work being done. There was evidence in this case, the court continued, that the employee sustained a hernia on the day in question, that the injury occurred suddenly and at a definite time and place that it was an unusual result of the work being done and that it did not result from a pre-existing condition. To render an injury accidental within the workmen's compensation act does not require that the strain be such that other

men would not attempt it or would anticipate probable injury therefrom. It simply means that the effort exerted, considering the position in which the workman was put by the work being done at the instant of the injury, was such that an injury, unanticipated and unforeseen, resulted to the workman. The Supreme Court accordingly believed that the industrial commission was justified in its award of compensation and affirmed that award—*Continental Baking Co v Industrial Commission (Utah)*, 69 P (2d) 268

Malpractice: Fecal Fistula Following Operation for Intestinal Obstruction—Gross suffered severe abdominal pains and the defendant, assisted by two other physicians performed an exploratory operation to ascertain the cause of the pains. Adhesions of the bowel were discovered which had caused an obstruction. The obstruction was removed and the wound was closed. Several days after the operation the patient began to vomit fecal matter. This condition continued for seventeen or eighteen days, "when one of the intestines ruptured and through this rupture the contents of the bowels and stomach forced their way through the incision and, in the region of the navel, which was at the upper end of the incision, there was created an opening which is termed a fistula." Thereafter the contents of the bowels discharged through this fistula. The defendant attended the patient at the hospital for about a month and thereafter called at his home on several occasions over a period of about three weeks. He then seems to have discontinued his connection with the case. Thereafter for about two years the fistula continued and the plaintiff had no normal bowel movements. Subsequently another physician operated, found an obstruction in the bowel where the previous operation had been performed, and eventually the patient was restored to a normal condition. The patient then brought suit for malpractice against the defendant. The jury rendered a verdict for the plaintiff but the trial court entered a judgment in favor of the defendant notwithstanding the verdict. The plaintiff appealed to the Supreme Court of Washington.

The principal question before the Supreme Court was whether or not the evidence was sufficient to take the question of the defendant's negligence to the jury. From the evidence, the court concluded that the jury had a right to find that at the time of the operation there was no infection, that some days after the operation there was an obstruction of the bowel, and that the patient was discharged from the hospital at a time when he needed further medical attention. In addition to this, the fact that a subsequent operation was necessary, while not sufficient in itself to take the case to the jury was some evidence of negligence. A physician, continued the court, who undertakes an operation on a patient is not justified, after such operation, in ceasing to attend the patient while further care and treatment are necessary. Furthermore, there are instances where facts alone prove the negligence and where it is unnecessary to have the opinions of persons skilled in the particular science to show unskilled or negligent treatment. Nor is it necessary that a case of malpractice be proved by direct and positive evidence. It may be proved by a chain of circumstances from which the ultimate fact required to be established is reasonably and naturally inferable. The evidence in the opinion of the court, created such a chain of circumstances in this case.

Accordingly the Supreme Court of Washington in a five to four decision, reversed the judgment and remanded the cause to the trial court with directions to enter a judgment on the verdict for the patient—*Gross v Partlow (Wash)* 68 P (2d) 1034

Accident Insurance: Death from Overdose of Barbitol—Where an insured, the Supreme Court of Kansas holds, takes barbitol without suicidal intent intending to take the quantity that he does take but in ignorance of the fact that the amount taken is lethal, and dies therefrom his death results from accidental means within the meaning of an insurance policy providing double indemnity if death results solely from bodily injuries caused directly exclusively and independently of all other causes by external violent and purely accidental means—*Spence v Equitable Life Assur Soc of United States (Kan)* 60 P (2d) 713

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Fatal Rheumatic Fever—Bland and Jones state that since 1921 about 1,500 children and adolescents less than 21 years of age have received hospital care at the House of the Good Samaritan for rheumatic fever and chorea. Data relevant to the 306 patients who have died are presented. Postmortem examination was made in seventy-four instances. The following conclusions are cited: 1 Rheumatic fever has been the principal cause of death and was directly responsible for the fatal issue in 250 instances (82 per cent). 2 The early years after the onset of the disease have proved to be a critical period. In approximately half (47 per cent) of the fatal cases death occurred during the first three years and in two thirds (62 per cent) during the initial five years. 3 Thereafter the extent of residual cardiac enlargement (dilatation) and, to a lesser degree, the rapidity with which it developed have served as the most reliable criteria of the severity of the preceding infection as well as an index of the future susceptibility of the individual patient to subsequent fatal rheumatic fever. 4 The age of the patient at the time of onset of rheumatic fever (or chorea) during the first fifteen years of life has been of no significance so far as subsequent longevity is concerned. 5 The manifestations of fatal rheumatic fever have been stressed and contrasted with the generally accepted clinical picture of the disease.

Subcutaneous Administration of Oxygen—Simpson and Barker observed the results of prolonged anoxia in thirteen epileptic patients who lived in rooms and were able to walk about and converse with their neighbors. The air breathed was under control as to humidity, temperature and oxygen content. The oxygen content of the inspired air was reduced gradually over the course of thirty-six hours in twelve cases. During the first thirty hours the average oxygen content of the air was 13.5 per cent and in the subsequent six hours it was lowered to a level that was thought safe for the particular patient from 7 to 9 per cent. The preliminary gradual induc-

tion of anoxia was used to prevent the undesirable effects of "mountain sickness." In no instance was a typical epileptiform seizure observed. To satisfy themselves that the presence of excess bromide in the blood of these patients (they were all under bromide therapy up to a few days before the tests were carried out) was not a factor in the suppression of seizures, the authors estimated the bromide content of the blood of every patient when he entered the chamber. In only two cases was the bromide level sufficiently high to have prevented spontaneous convulsions. In the remainder it was so low that it could not be detected by the Wuth method. The reaction of these patients to anoxia, as judged by the symptomatology and acid-base balance, was the same as one would expect and in no way differed from that of normal persons or of control dogs. The authors feel that the effect of anoxia by itself on epileptic subjects under ideal conditions is not a factor in the production of seizures.

- *Some of the More Uncommon Visceral Manifestations of Syphilis G M Piersol Philadelphia—p 19
- The Syphilitic with Negative Wassermann F J Eichenlaub Washington D C—p 24

Visceral Manifestations of Syphilis—Although syphilis of the lungs, stomach and kidneys is relatively infrequent, it is of definite clinical importance nevertheless and its diagnosis may be readily overlooked unless the possibility of its occurrence is kept in mind. The three types of changes seen in acquired pulmonary syphilis, as stated by Piersol, are gummas, areas of consolidation and catarrhal inflammation and chronic fibrosis. The diagnosis of pulmonary syphilis is difficult and is usually arrived at by exclusion. Cases of this kind are nearly always looked on as instances of tuberculosis, especially if the lesion happens to be apical. In arriving at the diagnosis of pulmonary syphilis, the following criteria are of some value. The patient presents other evidences of syphilis, the lesion is limited to the root or base of the lung, repeated and careful sputum examinations carried out over a considerable period must be consistently negative for tubercle bacilli, the Wassermann reaction must be definitely positive. Although gastric symptoms are exceedingly common in syphilis, actual syphilis of the stomach is uncommon. Before the diagnosis of gastric syphilis is made it should be borne in mind that gastric lesions of nonspecific origin frequently exist in persons who give a positive Wassermann reaction. The most positive proof of the existence of syphilis of the stomach is histologic and bacteriologic. The diagnosis of gastric syphilis rests on a combination of clinical features, in conjunction with characteristic roentgenologic observations, a positive Wassermann reaction, a positive therapeutic test and on microscopic and bacteriologic examinations. The types of gastric syphilitic lesions are diffuse syphilitic gastritis, syphilitic ulcers and gastric gumma. Syphilis of the kidney may manifest itself in congenital syphilis as well as in the course of early or late acquired syphilis. *Spirochaeta pallida* is capable of inducing characteristic renal lesions, and a true syphilitic nephritis does exist. The invasion of the kidney by the specific organism of syphilis cannot be denied and it is not unreasonable to believe that the kidney may suffer definite damage. Acquired renal syphilis, acute syphilitic nephritis and chronic renal syphilis have been observed.

- Proper Pre-cribing E C Denny Milton—p 75

Blood Pictures of Patients with Intestinal Disease—Borgen discusses cases that illustrate types of pathologic processes that occur in the large intestine in some, rather definite changes were found in the blood and in others, in which the

patients were seemingly as ill or more ill, there were no demonstrable changes in the blood. These two groups of cases are compared according to the type of management and progress of the patient. In two cases of severe septic type of thrombo-ulcerative colitis there occurred an identical blood picture, although in one case the history was of two years' duration and in the other only six weeks. The two patients were similarly ill, as far as degree of sepsis was concerned. Both patients recovered. One patient has been in good health for more than five years, the other, for a year. The blood picture was that of a hemoglobin deficiency type of anemia associated with reduction in the total number of erythrocytes and a relatively normal number of leukocytes, but the striking thing about the differential count was the marked shift to the left of polymorphonuclear leukocytes. The great predominance of non-filamented polymorphonuclear cells was also noteworthy. Some instances have occurred in which all the leukocytes, and frequently nearly all, have been nonfilamented polymorphonuclear leukocytes. In a case of hemorrhagic thrombo-ulcerative colitis the tendency toward hemorrhage was striking. Literally, bed-pansful of blood were passed and a very low content of vitamin C was found in the plasma. The marked reduction in excretion of vitamin C was noteworthy. The average normal content of vitamin C in the plasma has been recorded as 1 mg and excretion in the urine as 20 in a twenty-four hour specimen. Case 4 (chronic thrombo-ulcerative colitis with colonic scarring) is illustrative of the first type of chronic ulcerative colitis, in which the disease has burned itself out and, while much damage of the intestine has occurred previously, the present difficulty is largely a mechanical one. The blood picture was essentially normal in spite of a constant, severe diarrhea, to the extent of fifteen to twenty evacuations daily for two years. In a case of regional ileocolitis the blood picture was essentially normal in spite of severe obstructive disease at the ileocecal junction. The disease was inflammatory in nature and was associated with much scar tissue. In a case of diffuse polyposis, in spite of continuous diarrhea and severe bleeding from a polypoid mucous membrane for a year, no changes in the blood picture could be detected. Case 7 represents the timeworn story of anemia associated with carcinoma of the right side of the colon and case 8 illustrates that this type of anemia has been mistaken frequently for pernicious anemia. A case of actinomycosis of the sigmoid illustrates another type of blood picture commonly found in various types of severe, long standing perforating lesions of the colon. There was a persistent leukocytosis without the marked toxic features as expressed in other cases by the ratio of filamented to nonfilamented forms of the polymorphonuclear neutrophilic leukocytes. The high sedimentation rate of erythrocytes was also noteworthy. The severity of the disease was well illustrated by its prolonged course and by the appearance of the roentgenograms. The cases illustrate that in at least two major lesions of the intestine there is associated rather a characteristic blood picture. While the extent of changes in the blood varies in patients who have thrombo-ulcerative colitis, in the main the picture is quite characteristic. So, too, when there is a change in the blood picture in persons who have cancer of the right side of the colon, it is rather characteristic.

Progressive Postoperative Gangrene of the Abdominal Wall—Since most septic operative wounds of the abdominal wall are amenable to ordinary treatment and progressive postoperative gangrene of the abdominal wall is rather rare in the experience of the average surgeon and its early recognition and treatment are important, Hiebert lists the main features of this now apparently established clinical entity: progressive necrosis

about an operative abdominal wound, which does not respond to the ordinary methods of treatment, severe local pain and tenderness, slight rise in temperature or leukocytic reaction, general mental depression of the patient. The etiologic organisms are streptococci and staphylococci. Treatment short of complete cauterization excision of the entire lesion is likely to be inadequate.

New England Journal of Medicine, Boston

- *Useful Type of Light Waterproof Cast Preliminary Report A. Thorndike Jr. and W. E. Garrey, Boston—p. 205
- Surgical Treatment of Abdominal Fistulas S. F. Marshall and F. H. Lahey, Boston—p. 211
- Early Diagnosis of Schizophrenia by the General Practitioner D. E. Cameron, Worcester, Mass.—p. 221
- Social Security and the Physician C. A. Sparrow, Worcester, Mass.—p. 225

A Light, Waterproof Cast—Thorndike and Garrey state that the makers of cellulose products have developed a very hard, light, waterproof material for making box toes for shoes, adding boric acid to the cellulose compound rendered it but little more inflammable, when dry, than wood. The hard box toes were produced by molding a fabric impregnated with this compound while it was moistened with a solvent. Using this somewhat crude material, the authors constructed a satisfactory cast for a patient, who wore it daily in the water for five weeks. Numerous trials were carried out by impregnating various fabrics with the compound. The present most acceptable product is rolled, tinted, unbleached cotton sheeting, cut on the bias in widths of 2 and 3 inches and supplied in lengths of 10 yards. These bandages, correctly moistened with the quick-drying solvent, are supplied in hermetically sealed cans. The casts made from this material are far lighter than plaster, extremely hard, waterproof and pervious to x-rays. The cast takes on the average from thirty to forty minutes to harden sufficiently for the patient to be dismissed, and a longer time before it cannot be indented. The authors have used this material to make numerous casts for the upper extremities, both molded and circular, for fractures of the carpal bones, Colles' fracture and fractures of both bones of the forearm and to make three shoulder spicas for fractured humeri. The method of application is similar to that adopted with plaster of paris bandage, except that only three thicknesses are required, in certain areas of long or bulky casts, however, additional reinforcing strips or circular layers may be required to counteract stresses or strains. This product has one especial advantage: should the cast crack at any point it can be mended with additional lacquer (solvent) and bandage. In applying the casts, drying will be facilitated by placing three layers of gauze bandage over the skin or by using stockinet. The danger of applying the cast too tightly and not allowing for shrinkage is emphasized; this danger has been minimized by providing an impregnated cloth cut on the bias. Lamination may be prevented by painting the cast with some of the cellulose acetate lacquer (supplied in separate cans) the day after its application.

- Surgical Intervention in Acute Laryngeal Obstruction C. B. Flier Monroe, La.—p. 489

Fatal Tularemia—Matthews reports three fatal cases of tularemia in which postmortem examinations were done. He summarizes the chief features of seven additional cases in which postmortem studies were made which were not included in the review of the twenty-one cases made by Bernstein in 1935. The gravity of clinical signs of pulmonary involvement in the con-

of tularemia is emphasized by the fact that lesions of the lungs were present in twenty-four of the cases examined post mortem. The type of pulmonary lesion has varied, described as lobar pneumonia, abscess, cavitation and pleurisy with or without effusion. In earlier studies of necropsy material only the caseous lesions were considered to be due to tularemia. The outlying and more diffuse pneumonic patches were interpreted as secondary bronchopneumonia. More recently the demonstration of *Bacterium tularense* in the pulmonary exudate has furnished strong support for the view that the exudative pneumonia, as well as the caseous, is due to the tularemic infection. The author was able to stain bacteria, morphologically consistent with *Bacterium tularense*, in the pulmonary exudate of only his first case. Notwithstanding the indication that all types of pulmonary lesions in tularemic infection are due to this cause, it should be emphasized that a coexistent bronchopneumonia of other bacterial origin may be present, as was illustrated in one of Bernstein's cases. Attention has repeatedly been called to the resemblance of pulmonary tularemia to pulmonary tuberculosis. It is likely at times that pulmonary tularemia has been mistaken for tuberculosis. The microscopic changes closely resemble tuberculous caseous pneumonia except that they do not suggest distribution by aspiration. Tularemic involvement of the central nervous system is not an unimportant feature of the visceral pathologic changes. The postmortem data indicate that the most common sites of tularemic lesions are the skin, lymph nodes, lungs, spleen and liver. Isolated examples of tularemic lesions have been recorded in practically all the organs.

- *Selenium as Potential Industrial Hazard. H. C. Dudley.—p. 281
- Acute Response of Guinea Pigs to Inhalation of Methyl Isobutyl Ketone. H. Specht.—p. 292
- *Quality of Drinking Water on Trains. Note. A. P. Miller and E. C. Garthe.—p. 300

Selenium as Potential Industrial Hazard—Dudley lists the industries which may have unrecognized hazards due to the processing of selenium bearing materials. They are those engaged in glass decolorization, production of ruby glass, red and yellow glazes and paint and ink pigments, production and coloring of plastics, alloying of machinable stainless steels and free machining of copper base alloys, production of rubber accelerators and antioxidants, fireproofing of electric cable, and making photo electric apparatus and chemicals.

Quality of Drinking Water on Trains—From Sept. 14, 1936 to Feb. 15, 1937 Miller and Garthe had 1,090 samples of drinking water from coolers and other containers on trains operating in interstate traffic collected by trained men under the supervision of Interstate Sanitary District I at two large terminals in New York City and three smaller ones in Hoboken

and Jersey City, N. J. Samples were taken from all types of cars and trains without any attempt to be selective. Samples showing three or more 10 cc. tubes positive for the coliaerogenes group were considered as unsatisfactory. Along with the determination of organisms of this group the total bacteria per milliliter growing on agar at 37 C. was obtained. At no time did more than two hours elapse between the collection and testing of a sample. The percentages of samples showing three or more 10 cc. tubes positive for coliaerogenes for railroads 1 and 3 are considerably higher than for all others except 4, and the percentages of all three of these roads are in excess of the average for all samples tested, two of them considerably so. It is known that the sources of water supplying these lines are satisfactory, and that, if the water is safely handled, it should reach the consumers in good condition. Therefore, these results indicate that at least two of the railroads are inefficiently cleaning the containers on their cars or are handling the water after it leaves the supplying municipality's system in such a careless and insanitary fashion as to permit contamination.

Nonvenereal Vaginitis—Cornell suggests the following treatment for nonvenereal vaginitis (*Trichomonas vaginalis* vaginitis). He prescribes 100 tablets of a preparation containing acetarsone (Devegan) and instructs the patient to insert one tablet in the vagina nightly after retiring. The patient is warned against having sexual intercourse throughout the course of treatment unless a condom is used. She is not to take douches. She should keep the labia clean by frequent washing, since the tablet disintegrates and is discharged from the vagina. If allowed to dry on the hair, it is difficult to remove. The patient is to return to the office on the first, third and fifth day of her menstrual period. At this time the menstrual secretions are cleaned out and three or four tablets are inserted into the upper part of the vaginal vault. When the period is finished, the patient may resume home treatment. After the fourth menstrual period the home treatment is discontinued but the patient is to return to the office one week after she stops flowing. The secretions at this time are cleaned out and, if *Trichomonas vaginalis* is not found the patient is instructed to return in ten days for a retest. If the test is negative again, the patient returns again after her next menstrual period for another test. The patient is considered cured if no evidence of *Trichomonas vaginalis* is found on this visit. If a patient who has finished the course of treatment and has been pronounced cured suffers a recurrence of vaginitis following sexual intercourse without the use of the condom the husband should be considered a trichomonas carrier even though the organism is not found in his prostatic secretions. He should be given treatment. The woman should be treated in the same manner as before for at least two or three months and retested thereafter.

Trauma and Progressive Muscular Atrophy—Little is known about the etiology of progressive muscular atrophy, but its association with trauma in a small percentage of cases has been described by eminent neurologists during the past decade. These authors divide such atrophies into different groups: muscular atrophy localized to the region of the muscles in the neighborhood of the injured joint, amyotrophy ensuing rapidly on the injury and developing on a paralytic background and slowly developing wasting preceded by any notable paralytic phenomenon and not associated with sensory troubles or reflex abnormalities. Sutton states that from 1925 to 1934 thirty-one cases of progressive muscular atrophy were admitted to the Bristol Royal Infirmary, and in only three of these do the case notes include a history of injury. It is probable that this number would have been higher but for the fact that many physicians do not inquire about a previous history of injury in such cases because the importance of this is not recognized. There is no evidence in favor of the idea that trauma merely "pulls the trigger" in cases in which there is a congenital predisposition, nor is there any practical support for the suggestion by Thiemann that an ascending neuritis occurs which ultimately involves the anterior horn cells and so produces the muscular atrophy. Localized reflex wasting after injuries of bones and joints is an entirely different condition. The problem here is one of widespread progressive muscular atrophy developing in some cases years after a severe injury. It seems to the author that one is bound to assume that a molecular disturbance of the brain or cord is occasioned by the injury. A mysterious feature of the disease is the lack of correspondence between the pathologic process and the symptomatology. It is possible, therefore, that degeneration of the Betz cells in the cortex and of the anterior horn cells in the cord may occur some years after the injury before clinical signs become manifest. There is evidence that trauma is a definite etiologic factor in some cases of progressive muscular atrophy.

Infantile Edema—From April to October 1937 thirteen children with infantile edema were admitted to the Native Hospital, Kiambu. All were between the age of 1 and 4 years; eight were boys and five girls and all were African children from the Kiambu native reserve. The chief symptoms according to Bell were generalized edema in all cases with one exception; depigmentation of the hair in all cases; photophobia in six cases and rashes in all. In several boys the penis and scrotum were so swollen as to interfere with micturition. The children

all whined and moaned and resented being handled, being compelled to lie still, covered up with a sheet or blanket. No definite history of the onset of the disease could be obtained. In most of the cases marked enlargement of the abdomen was noted. Coryza was observed in six cases, septic skin rashes in seven, ulceration of the penis and vulva in five cases. The blood in all cases showed anemia. Of the thirteen patients, one died six hours after admission, three went home slightly improved and nine were "cured." All the patients were treated with one-half drachm (2 Gm.) of an autolyzed yeast preparation three times a day, tomatoes, orange juice and cod liver oil with milk, beans and gruel. Three patients received this treatment only and the remaining ten were treated (in addition) by daily injections of 2 or 3 minims (0.15 cc.) of liquid epinephrine hydrochloride injected subcutaneously. Of the ten patients so treated one died after admission, but the remaining nine showed marked improvement in a short time, most of them after five injections were running about the ward and playing in the hospital grounds like normal children. In ten days most of the edema regressed, the skin all but returned to normal if slightly lighter in color and was a little more patchy than normal. The hair too in most cases became stronger, curly and dark. The hemoglobin average was now 70 per cent and the stools were improved. The improvement in the three cases treated without epinephrine was slight and in no way resembled the results obtained with it.

Myeloid Leukemia Treated by High Voltage Roentgen Therapy—Mallick and his co-workers cite a case of chronic myeloid leukemia which has been greatly benefited by high voltage roentgen therapy. There are two points at issue in this case: whether tuberculosis bears any relationship to this disease, for it has been noticed more than once that in some of these cases in which an earlier tuberculous infection has been overcome by rest and treatment myeloid leukemia developed later on, and whether the beneficial effect in this case was brought about only by exposure mainly of the bones. The X-ray exposure directly affects the hemopoietic tissue and thereby checks its malignant activity. This explains the benefit only in the present case but fails to explain the achievements of other clinicians whose patients have benefited from either exposure of the spleen alone or by exposure of the whole body, alternately ventral and dorsal sides without especially taking up the bones or the splenic region. Mallick believes that though the reduction in the number of white cells is the most apparent phenomenon it is not the fundamental one in the mechanism of improvement. This destruction occurs in crisis analogous to that occurring in the spontaneous leukocytic crisis in all leukemias, the difference being that in those which occur after treatment the X-ray provokes a leukocytic increase which in turn provokes the crisis of destruction. He gives figures by taking daily white counts and proves how after a marked rise in leukocytes a sudden crisis which greatly reduces the count occurs. To Isaacs it appears that the good effect of high voltage roentgen therapy is due to stimulation of the formation of leukocytes and their maturation which subsequently ends in complete destruction of the maturing cells.

- Treatment of Diabetes Mellitus by Means of Diets Rich in Carbohydrates A Baisset and C Darnaud —p 138

Erythroblastic Anemia—According to Caminopetros, the facts collected so far indicate that erythroblastic anemia occurs especially in the countries of the eastern Mediterranean. It is a familial disorder which attacks children and usually ends in death. The first cases were observed by Cooley among the American-born children of Greek, Italian and Syrian immigrants. This author called attention to a special kind of bone lesion which can be detected in the roentgenologic examination of the skeleton. Since Cooley's report, other cases have been observed in America, always in children of Greek, Italian and Syrian immigrants. Only recently several cases have been described in Mediterranean countries, particularly Italy. In Greece, as in other countries, the disorder is confused with leukemic anemia or the other less acute anemias. The author investigated the incidence of this disorder in Greece. The total number of cases studied by him was thirty-six. He says that, in addition to the characteristics already known (erythroblastosis, Mongolian facies and osseous changes), there is augmentation in the resistance of the erythrocytes. To him this symptom seems so essential for erythroblastic anemia that it alone justifies the diagnosis, just as the diminution of the resistance identifies familial hemolytic disease. He directs attention to roentgenologic changes of the cranium. The fact that these changes and a complete absence of Mongolian facies characterize a number of cases induced him to separate from Cooley's anemia a new form, under the name of anemia of geophagists. Then he directs attention to a form of erythroblastic anemia, characterized by elongated forms of erythrocytes, recalling the sickle-shaped erythrocytes found in anemic Negroes. Finally the author studied a whole series of secondary anemias which, as is proved by their comparison with erythroblastic anemia, is already known under the term of von Jaksch-Luzet's anemia, which is entirely different from primitive erythroblastic anemia. The osseous changes in erythroblastic anemia are absolutely specific. The osseous malformations of the face and cranium result from the disease itself, and thus have to be differentiated from the other characteristics of the Mongolian race. The author points out further that hidden pathologic deficiencies have been detected in the apparently healthy parents and siblings of patients, such as the augmentation in the resistance of the erythrocytes and changes of the bones, two signs of erythroblastic anemia. This fact proves the possibility of a hereditary transmission for this alteration of hemopoiesis. The examination of the resistance of the erythrocytes constitutes a sure method to detect the apparently healthy carriers of the disease among the members of the families of the patients and thus provides a basis for a social prophylaxis, that is, by forbidding procreation. The hereditary transmission was proved also by the identity of blood groups. Malarial therapy is the only therapeutic method by which can be obtained an arrest of the abnormal and excessive functional activity of the hemopoietic system.

- Intradermal Injections of Histamine Procedure of Exploration of Tegumentary Circulation in Surgery of Members P Goinard —p 128

Injection of Histamine in Obliterating Arteritis—Weissenbach and Perles tried the intradermal injection of histamine, which they had been employing to counteract the pains of the contractures of rheumatism, in the treatment of chronic obliterating arteritis. This seemed justified in view of the analgesic and vasomotor action of histamine. In two cases the

results were such that they feel justified in calling attention to this treatment. They employ a solution of histamine hydrochloride with a content of 0.5 mg per cubic centimeter. The adaptation of the doses to the individual patients is important, because many of these patients have hypertension and fragile arteries. The dose of 0.5 mg per injection should never be exceeded. The patients felt relieved at once. The pain in walking was improved after the first treatment and the spontaneous nocturnal pains were relieved the first night after the treatment. The first patient was given five injections in the course of two weeks. The second patient was given two injections during the first week and one injection each during the following three weeks. In both patients the functional improvements persisted long after the treatment. In the first patient, eighteen months has elapsed since the histamine treatment and in the second patient six months, and both are still free from pain.

- *Behavior of Calcemia During Digestion in Relation to Different Grades of Gastric Acidity C Cella —p 25
- Clinical Study of Six Cases of Choleperitoneum G Brendoln —p 49

Behavior of Calcemia During Digestion—Cella has reported the effects of induced calcemia on gastric acidity and gastric chemism in normal persons and in patients suffering from gastric and extragastric diseases. His article was reported in the *Archivio italiano delle malattie dell'apparato digerente* (6 381 [Aug] 1937, abstr THE JOURNAL Oct, 30, 1937, p 1494). The author now studies the effects of gastric acidity and gastric chemism on calcemia. He followed the behavior of calcemia during digestion in fifty-one patients suffering from gastroduodenal diseases and in another group having diseases other than gastroduodenal. He concludes that the curves of calcemia and of gastric acidity during digestion follow an independent course in patients who have increased gastric acidity (peptic, duodenal and juxtaepiloric ulcers, gastroduodenal stenosis and hyperacid gastritis) and in patients with normal gastric acidity (those with other than gastroduodenal diseases). The curves of calcemia and gastric acidity in patients with diminished gastric acidity and with anachlorhydria, when they are constant during digestion, run parallel to each other. If acidity increases in the gastric secretion of patients who are suffering from anachlorhydria, calcemia diminishes. In the fifty-one patients who had gastroduodenal diseases normal calcemia was found in forty-two cases, increased calcemia in seven and slightly diminished calcemia in two. In the majority of cases, calcemia does not change during digestion. In rare cases there are variations which do not exceed 17 mg of calcium for each hundred cubic centimeters of blood.

- Mechanism of Weltmann's Reaction of Coagulation of Blood Serum Relation Between Reaction and Proteins in Blood Serum in Pulmonary Tuberculosis U De Michelis and E Massobrio —p 155
- *New Factor in Pathogenesis of Chronic Bronchitis in Children and in Development of Pulmonary Tuberculosis Zula Franzoso Pirani —p 158
- *New Method of Homogenization of Search for Tubercle Bacilli in Sputum A D Arsenzo —p 159

Diseases of Respiratory Tract—Franzoso Pirani states that she has found eggs of parasites (ascarides, Trichocephalus and Ancylostoma) in the feces of all children who are suffering from a special type of chronic catarrhal bronchitis, as well as in those of adults who show sudden evolution of latent pulmonary tuberculosis. Bronchitis in these cases is diffused to one or both sides and the patients are anemic and dyspeptic. The roentgen examination of the thorax shows shadows at the hilus of the lung and sometimes adenopathies. Latent tuberculosis develops in one or both lungs. Controlling intestinal parasitism by administering antiparasitic treatment to the patients improves the respiratory diseases and the general condition of the patients. According to the author, intestinal parasitism is the cause of nontuberculous diseases of the respiratory tract and of the development of latent pulmonary tuberculosis. The fact is due

to the biologic cycle of intestinal parasites. The eggs in the intestine are acted on by gastric juices, a process by which the larvae are set free. The latter go through the intestinal wall, portal blood and blood vessels to the lung and pass through the parenchyma of the organ and the respiratory and digestive tracts back to the intestine, where they develop into adult forms. In rare cases the larvae perforate the lung parenchyma through the diaphragmatic pleura. The author emphasizes the importance of the knowledge of the part of intestinal parasitism in the pathogenesis of pulmonary and bronchopulmonary, tuberculous and nontuberculous diseases, especially for the diagnosis, prevention and treatment of the diseases.

Homogenization of Tubercle Bacilli in Sputum—D'Arienzo's method is as follows: A solution is prepared with 8 cc of distilled water, 15 cc of a 1 per cent solution of phenol and 0.5 cc of ammonium hydrate. Equal parts of the solution and of sputum are mixed, homogenized and placed in an incubator at 37 C. After ten or twelve hours the mixture is centrifugated. The sediment is placed on a glass slide previously covered with serum or with egg albumin and stained with Ziehl-Neelsen's dye. In thirty samples of sputum the author obtained the following results: All the samples gave negative results with the simple method of examination of sputum, twenty of the thirty samples gave positive results for the presence of tubercle bacilli with the method in which a strongly alkaline solution of sodium hypochlorite was used and twenty-three of the thirty samples gave positive results to the author's method. The technique is simple and the method useful.

Prevention of Warts. F. Bazan and E. Sujo—p. 350

Sodium Chloride in Pleuropulmonary Diseases—Videla and his collaborators found that the exudates of serofibrinous pleurisy and the blood of patients suffering from the condition contain an increased amount of sodium chloride (440 mg and 370 mg of sodium chloride for each hundred cubic centimeters of exudates and total blood, respectively). The blood of normal persons contains 290 mg of sodium chloride for each hundred cubic centimeters of blood. The variations of sodium chloride in the pleuritic exudate and in the blood of the patients are in relation to each other. The administration of intravenous injections of hypertonic solution of sodium chloride in daily progressive doses of from 10 to 20 cc of the solution, up to a total number of from six to nine injections, diminishes the amount of sodium chloride in the pleuritic exudates and in the blood of the patients and stimulates reabsorption of pleurisy in acute pleuropulmonary diseases if pulmonary tuberculosis in evolution is not present. The authors believe that the increase of sodium chloride in the pleuritic exudates and in the blood of the patients shows dysfunction of the tissues in fixing sodium chloride. Satisfactory results of the treatment are reported in five cases.

Sensitivity to Digitalis in Cardiac Impairment—

Schulze points out that Frommer and Bauer were able to demonstrate that the anatomic lesions in the cardiac muscle which are produced by toxic doses of digitalis are the cause

of the increased sensitivity to further medication with digitalis. The author himself had made the observation that hearts which had become impaired by the toxins of diphtheria had an increased sensitivity to the glucosides of digitalis. It seemed justified to assume that it was not the substance causing the lesion but rather the lesion itself which was responsible for the increased sensitivity to digitalis. To gain a better insight into this problem, the author studied the hearts of cats that had been made anemic and then subjected to work tests. These cats as well as their isolated hearts, show an increased sensitivity to digitalis. On the basis of these experiments and of earlier observations, the author assumes a relationship between the severity of the anatomic lesions in the myocardium and the degree of sensitivity to digitalis.

Meimicke Reaction in Tuberculosis—Spies reviews the literature on the Meimicke immunity reaction in tuberculosis and reports the results he obtained with this reaction in 232 cases. He found that when the Meimicke reaction was made only once it was positive in 102 cases, or slightly more than 40 per cent. He gained the impression that the positive outcome of the reaction is dependent on a demonstrable excess of antibodies. For this reason the reaction is negative nearly always in early infiltrates, miliary tuberculosis and generalized forms and in the predominating number of cases of severe acute exacerbations and hemorrhagic disseminations. Taking into consideration the outcome of the Meimicke reaction in the course of the tuberculous process, the conclusion is reached that the diagnostic value of the reaction is slight. In extending the serologic examinations over longer periods, it is found that the Meimicke reaction permits only a catamnestic evaluation of the disease process without allowing in most cases an estimation of the further development of the tuberculosis. Only in case of an acute severe exacerbation does the Meimicke reaction run exactly parallel to the course of the disease. The author discusses the present status of the antigen antibody problem during tuberculosis.

*Cevitamic Acid in Serum Under Normal and Various Pathologic Conditions. H. E. Nielsen—p. 20

Cevitamic Acid in Serum—For determination of the cevitamic acid in the blood Nielsen used Lund and Lieck's method, based on the decoloration of methylene blue solution under powerful illumination when cevitamic acid is present. In 100 normal persons on ordinary Danish diet examined from April to September the lowest cevitamic acid value in the blood, an average of about 0.30 mg per hundred cubic centimeters, was found in April and May, and the highest, an average of about 0.40 mg, in September. The Gothlin test is not specific for avitaminosis C and is most significant in cases in which it is positive and becomes negative under treatment with vitamin C. Determinations in April of the cevitamic acid values in forty pregnant and forty-one nonpregnant women in the same age group showed considerably lower values in the first group. Comparative determinations in the maternal and the fetal blood (umbilical cord blood) directly after birth revealed a deficit of cevitamic acid in the maternal blood and in the fetal blood an excess of up to eight times the amount in the mother's blood. In twenty-eight patients with gastric achylia the cevitamic acid values were lower than in normal persons during the same month. Deficient acidity in the stomach is a frequent anomaly in disorders due to vitamin deficiency, such as avitaminosis A, B₁ and B₂ in which the anomaly often disappears on addition of the respective vitamins to the diet. In twenty patients with gastric or duodenal ulcer of pylorogastritis the cevitamic acid value in the serum in April was 0.23 mg per hundred cubic centimeters. A possible connection is seen between the frequent springtime appearance of symptoms in these patients and the low cevitamic acid values in the blood at that time. In a case of infantile scurvy with cevitamic acid value in the serum of about 0.05 mg per hundred cubic centimeters in spite of the administration of lemon juice steady improvement resulted on subcutaneous administration of cevitamic acid.

UNDERGRADUATE INSTRUCTION IN PREVENTIVE MEDICINE

J G FITZGERALD, M D

Director School of Hygiene and Connaught Laboratories
University of Toronto
TORONTO

This survey has been undertaken to obtain information respecting the scope and content of undergraduate teaching of preventive medicine, public health and hygiene in any or all departments of medical schools in the United States and Canada and in twenty-four European countries. The survey has occupied a period of one year—Sept 15, 1936, to Sept 14, 1937.

The countries visited include

- | | |
|------------------|------------------------------|
| 1 Austria | 15 Irish Free State |
| 2 Belgium | 16 Italy |
| 3 Bulgaria | 17 Latvia |
| 4 Canada | 18 Lithuania |
| 5 Czechoslovakia | 19 Norway |
| 6 Denmark | 20 Poland |
| 7 Estonia | 21 Rumania |
| 8 Finland | 22 Sweden |
| 9 France | 23 Switzerland |
| 10 Germany | 24 United States of America |
| 11 Great Britain | 25 Union of Soviet Socialist |
| 12 Greece | Republics |
| 13 Holland | 26 Yugoslavia |
| 14 Hungary | |

Sixty-four universities in Europe and twenty-one in the United States and Canada were visited.

Because of the fact that a survey of medical schools in the United States and Canada was begun in 1934-1935 and continued through 1935-1936 by the Council on Medical Education and Hospitals of the American Medical Association with the cooperation of the Association of American Medical Colleges and the Federation of State Medical Boards of the United States, the number of institutions visited by us in the United States was definitely limited.

The Council on Medical Education and Hospitals made the information obtained in this survey available to Dr C E Smith and me. It consists of completed questionnaire forms (form R, Preventive Medicine and Public Health) submitted by sixty-nine medical schools. In addition we have been provided with notes made by Dr H G Weiskotten during his visits to fifty-four schools, as a representative of the Council on Medical Education and Hospitals.

There were, in the United States and Canada in 1936, eighty-seven medical schools. Fifty-four of the

sixty-nine schools from which completed questionnaires were obtained were visited and reported on by Dr Weiskotten. There were fifteen schools not visited by him which submitted information. Of these, twelve were visited by one or both of us. The total number of medical schools in the United States which either completed forms or were visited and reported on by Dr Weiskotten during 1934-1935 and 1935-1936 was seventy-one.

It is of some interest to observe that in the United States, to judge from these reports, there are in these seventy-one schools only eighteen that have full time university departments of preventive medicine, public health and hygiene. In Canada there are nine university medical faculties, and in five of these there are whole time departments. In twenty-five additional medical schools in the United States preventive medicine, public health and hygiene are included in or combined with bacteriology. In one Canadian university this is also true.

In the United States the following medical schools may fairly claim to have university departments of preventive medicine: Harvard, Michigan, Women's Medical College of Pennsylvania (combined with the Student Health Service), Stanford, Yale, Iowa, Tulane, Minnesota, Columbia, Cornell, New York University, Cincinnati, University of Pennsylvania, Meharry, Vanderbilt, California, Tufts and the Medical College of Virginia. With respect to the two last named, there may possibly be some question as to whether they should be so described.

In Canada there are whole time university departments at Western Ontario, Toronto, Queen's, McGill and Dalhousie¹. All these have been visited and reported on by my colleague Dr C E Smith.

Combined or incomplete departments of preventive medicine, public health, hygiene and bacteriology existed at the time these surveys were made in the medical schools in the following universities: Chicago, Baylor, Syracuse, Western Reserve University of Virginia, Texas, Boston, Colorado, Georgetown, George Washington, Howard, Georgia, Loyola, Northwestern, Illinois, Louisville, Missouri, St Louis, Washington, Duke, Oregon, Jefferson, Medical College of the State of South Carolina, New York Homeopathic and Creighton (?)—twenty-five in all. In Canada a similar arrangement exists in the University of Alberta.

It is true that in some of the medical schools included in the foregoing categories the personnel may have duties in health departments of states, provinces or cities as well as university appointments. In general such arrangements are advantageous rather than the reverse.

Read before the Thirty-Fourth Annual Congress on Medical Education and Licensure, Chicago, Feb. 14, 1938.
Based on study undertaken in 1936-1937 by the author and Dr C E Smith of Stanford University School of Medicine for the Rockefeller Foundation.

¹ In addition there is a department of social medicine at the University of Montreal.

EVOLUTION OF THE TEACHING OF HYGIENE

It may be profitable at this point to turn back and review briefly the evolution and development of the teaching of hygiene.

University concern with the teaching of hygiene, public health and preventive medicine dates back about seventy years. There seems to be general agreement that the first chair of hygiene was created in Munich in 1865 and was filled by Pettenkofer, then a worker in the Institute of Physiology. The first institute of hygiene, it is claimed, was established in Budapest in 1874, and Fodor was the first professor. In 1875 Vienna created an institute of hygiene, and in Munich in 1879 a separate institute was established for Pettenkofer. All this occurred in the period before bacteriology had begun its onward march. Pettenkofer and Fodor were names to conjure with.

The complete domination of the original concepts of Pettenkofer and Fodor concerning the scope of hygiene (regarded as a distinct scientific discipline in the medical sciences), and especially the nature of its content, is a fact of profound importance. To this day, in many medical schools, the introduction to the subject is effected by a detailed consideration of the environment of man and the various factors concerned therein. How many generations of medical students have been lulled to rest while listening to lengthy disquisitions on air, soil and water? These facts must be clearly recognized if the present position is to be properly understood. Much that is now struggling to find expression in the teaching of preventive medicine would long ago have been included in the program of medical studies if it had not been for this background.

Crystallization and later fossilization of the "environmental notion" has indubitably retarded progress in the teaching of public health and preventive medicine. Dogma and authority laid a dead hand on hygiene!

The commencement was not inauspicious. The original material on which the teaching was based, namely, some elements of meteorology, physics and chemistry, was expanded to embrace the new field of bacteriology or microbiology and that portion of physiology concerned with the study of growth and nutrition. Robert Koch was the first professor of hygiene in Berlin (1885), Rubner was his successor (1891). This amazing conjunction of microbiology, physiology and biochemistry as the fundamental basis of hygiene must have aroused great hopes. Alas, microbiology, bacteriology, infection and immunity all went one way, physiology and biochemistry another, and each became independent disciplines in the medical schools. Research and teaching in both advanced in a marvelous fashion, the former constantly fertilizing the latter. The expanding and developing foundations of scientific medicine, ever increasing in strength and significance, were becoming more and more imbued with the spirit of inquiry. Physiology set the pace.

In the meantime, what of hygiene? Literally, it was what remained after the departure or desertion of microbiology and physiology! This was true of course only in the hygiene teaching departments of many medical faculties. Actually, outside, giant strides were being taken in the fields of public health and of social and preventive medicine. The excursions of the state into the domain of medicine, from the passage of the English Public Health Act of 1875 and the introduction of health insurance by Bismarck, were becoming more

and more frequent and significant. The health and social well being of man was a matter of increasing concern to governments.

The fundamental sciences furnished the means for these repeated advances of enlightened governmental and voluntary agencies directed against disease, poverty and ignorance.

Physics, chemistry and biology in their expansion and development furnished new principles and methods by which physiology, genetics and immunology could be employed in the prevention of disease, the prolongation of life and the mitigation of human suffering. Thus did research and investigation in many fields of preventive medicine contribute most significantly to the triumphant march of science during the past half century.

The development of epidemiology was the work of many hands. In the past hundred years, however, the contributions of two pioneers stand out—the studies of William Budd and of John Snow. They were made in the prebacteriologic era. The great contributions to microbiology of Pasteur, Robert Koch and Theobald Smith (to name but three in a great galaxy) have not lessened the significance of the work of the pioneer English epidemiologists. On the administrative side real progress has resulted from the accumulation of careful records and painstaking observations carried on for half a century. Chapin and others in the United States deserve special mention. They contributed to a better understanding of sources of infection. Much earlier, in the statistical field, William Farr and Francis Galton in Great Britain prepared the ground for later work in experimental epidemiology and the more prosaic department of public health bookkeeping.

The development of a new field of work, or its more intelligent cultivation, by Richard Cabot in Boston, between 1900 and 1905, was important. It was the creation or new use of an auxiliary to the clinic, namely, medical social service. Its purpose was to assist in gaining a clearer insight into the effects on health of environmental influences. The field of study was extended from the patient to his surroundings, work, play, income, intelligence, education and interests. What factors (which could not be elicited by the history or by clinical examination) contributed to the patient's ill health? In earlier times sisters of mercy, lady almoners or representatives of charity organizations concerned themselves with the care of the needy. Often ill health was a causative factor. Could poverty and ignorance or maladjustment influence physical disease?

Medical social service had definitely, as one of its functions, investigation of causative factors or untoward influences. Social insurance (health, invalidity and old age), chiefly in European countries, has had a phenomenal growth in recent years. The relation of this to preventive medicine is not unimportant.

The study of the early symptoms of disease in special institutions like the James Mackenzie Institute for Clinical Research at St. Andrews is obviously an important avenue of approach—a highway of preventive medicine susceptible of great extension. Mackenzie's vision conceived of something definitely realizable. Appointment of keen young investigators in clinical research at certain centers in England within the past two or three years may here be noted.

One other group of activities may next be briefly considered. With the organization of elementary school health services and university health service, there arose a demand for criteria in the effort to

physical fitness What was the range of normality? What were the boundaries of the normal when the health of school children, college students or clients seeking periodic health examinations was being explored? When presumed healthy individuals of any age were being examined for the earliest evidence of deviation from the normal, or being advised as to a way of life, in order to maintain the ideal of "*mens sana in corpore sano*," whose responsibility was it to educate doctors to discharge such duties? With what scientific facts should they be familiar? What methods of examination should be applied? Whose job was it in the whole group of medical sciences to concentrate a little attention on the study of normal, healthy human beings, in their work, in their play, at different ages, under various economic, social and environmental conditions?

If one is interested in the search for the normal range of many important physiologic functions so that an answer may be given to the question "Is this person in a condition of mental and physical health?" there is certainly even greater need for the formulation of suitable criteria for assessing states of nutrition

Now research into all these questions has been and is being done at present In physiology, biochemistry and anatomy there is phenomenal activity The advances in knowledge of hormones is an illustration of this When one turns to the clinical side of medicine equally noticeable progress is manifest To the advance of preventive medicine perhaps no other discipline has contributed more than pediatrics In the steady and long continued effort to promote infant and child health, as well as to gain a wider knowledge of healthful states, pediatrics in many university clinics has shown how preventive medicine may be practiced as well as preached Obstetrics, too, has contributed The importance of antepartum care is now everywhere recognized In most obstetric clinics it is taught and practiced, and the maintenance of the health of the prospective mother is really a part of the teaching of midwifery in the best medical schools General medicine has also in certain specialties, notably tuberculosis and venereal diseases, a fine record of achievement It is a far cry from the simple clinic of Calmette in Lille, with its attached "infirmieres visiteuses" or that of Philip in Edinburgh, to the tuberculosis dispensary of today

Surgery too (notably in the clinic of Wilkie in Edinburgh) has been exceedingly active on the preventive side, as has ophthalmology, in the development of methods for the prevention of blindness (such as the use of suitable prophylactics to eliminate ophthalmia neonatorum and the aid given to the movement for cataracts in sight saving)

Psychiatry has taken a leading part in the mental hygiene movement No field of medicine is more difficult of cultivation, none more important to explore and develop if possible In any event, psychiatric clinics and special sections in general medical clinics (in conjunction with psychology) are now committed to the task of learning more of the genesis and evolution of psychotic states and of what may be done to prevent their occurrence

It is abundantly clear that bacteriology and immunology are of prime importance in every further advance on that volume of preventable illness made up of communicable diseases There bacteriology and preventive medicine may and do effectively collaborate So much remains to be discovered concerning the etiology of

such widespread diseases as influenza (to mention but one of many) that the efforts of bacteriologists is unlikely to lessen opportunities for workers in the field of preventive medicine for many a long day

EFFECTIVENESS OF TEACHING

In the meantime, what of the teaching of hygiene? Was it fruitful, was it effective, did it intrigue its students whether in elementary schools, colleges or faculties of medicine? Let us be honest It did not! With a few notable exceptions, university medical schools had in their teaching departments of hygiene, surely reached the low-water mark of effectiveness when in ten or fifteen didactic lectures some elementary principles of physics or chemistry were employed in demonstrating a few unimportant facts regarding our surroundings, our clothing, our food and drink That constituted what was rather quaintly described as hygiene and sanitary science Of course, in many medical schools, some good, some bad and some indifferent, little or no attention was paid to hygiene and sanitary science, or even to preventive medicine, for that matter

Let there be no misunderstanding Man's environment is of profound importance Clear understanding of its dangers and its hazards and inquiry into their nature and how they may be circumvented are no mean fields of human endeavor Actually it has largely been a triumph for engineering That field of science employing the methods of biology, mathematics and mechanics has made a great and enduring contribution to human welfare It has been something real and effective in sanitary science North America has participated in this triumph to a notable extent Sedgwick and his school in Boston were among the pioneers

With the collaboration of biologists in the fields of entomology, parasitology and helminthology, medical scientists and engineers alike have also contributed to some magnificent advances in the conquest of disease Witness the achievements in malariology and tropical medicine generally! But it is not unfair to say that the inspiration did not derive from the medical teaching of hygiene

Perhaps the creation of the first important separate department of preventive medicine and hygiene in the Harvard Medical School in 1909 was not entirely unrelated to the activities in the neighboring center of higher learning, the Massachusetts Institute of Technology There Sedgwick labored In any event the Harvard development was momentous Previously in Europe, in the British Isles and in North America there had been conjoint chairs of bacteriology and hygiene, and where such existed public health aspects of bacteriology were often cultivated assiduously The University of Minnesota was a notable example of this

A reasonably complete and comprehensive picture of the situation in various parts of the world between 1900 and 1910 can be obtained by reference to medical school calendars and announcements of the period

It is probably true to say that the German institutes of hygiene (and similar institutes in countries in which university medical faculties were modeled on German lines) were most advanced They were independent university institutes They were staffed by persons who devoted themselves to teaching and investigation There were a number of journals for the publication of the scientific output of the workers in the field

In few other countries was the situation so promising at that period. Certainly in but few of them in 1900 were there institutes in the German sense.

The situation at the best was seen in those places where bacteriology and hygiene were combined and where the teaching was limited to a consideration of certain aspects of infection and immunity, to the study of communicable diseases and some reference to such environmental topics as bacteriologic and chemical methods employed in water purification and sewage treatment. If there was affiliation between such departments and health organizations, the situation was not without promise. It obtained in a number of institutions in North America. In Michigan in 1910, under the late Victor C. Vaughan, there was perhaps the best department on the German model in North America.

In the British Isles and in many British communities the subject was combined for purposes of university teaching with medical jurisprudence or legal medicine. There may not have been much logic in such an arrangement, but it often had the merit of affording a brilliant expositor with a first-rate opportunity of displaying his forensic talents or fascinating his auditors with the details of a local murder mystery. It was enjoyable but had not much to do with preventive medicine and hygiene.

Almost nowhere at that time was the instruction other than didactic. Examinations in hygiene, even where they were required, presented few terrors for the indifferent and none for the diligent student. Almost everywhere, outside German universities (and those like them, in adjacent European countries), the students held hygiene in low esteem.

Those who constitute the great bulk of medical practitioners today, who are 50 years of age or more, received no teaching whatever in hygiene worthy of serious consideration or, as medical students, did not hear of the subject at all. There is little wonder, then, that it is a "minor" subject in the opinion of mature physicians generally and that they are not greatly moved by the agitation or clamor for more instruction in preventive medicine.

This has naturally led to the conclusion on the part of not a few that preventive medicine, hygiene, public health, social medicine and the like need not be developed in independent departments or chairs but should be regarded simply as part of the subject matter of anatomy, biochemistry, physiology, bacteriology and the clinical branches. The arguments for and against this point of view are essentially those used by persons who do not believe in separate chairs or clinics or departments of subjects like pediatrics or psychiatry. They need not be elaborated. They are largely academic and lacking in reality. There are also those who, while admitting that it is desirable to teach preventive medicine to medical students, insist that there is no time for such instruction in an already overcrowded curriculum. The answer to that objection is that suitable rearrangement, rather than any addition to the program of medical studies, could and should be made. In a number of the best schools it has been done and is quite possible and practicable anywhere.

The proponents of the view that preventive and social medicine is most likely to be developed vigorously and satisfactorily, if recognized as a distinct discipline in the medical school, are those who believe that preventive medicine, in many of its aspects, is a responsibility of practically every department of the medical

school. They adhere, however, to the view that this business will be accomplished most thoroughly if some portions of the field (left largely uncultivated by other departments) are the responsibility of some one department. This may be called hygiene, public health, preventive medicine or social medicine. Preventive and social medicine is perhaps the least objectionable. But designations are less important than the job and the way in which it is done.

SUBJECTS TO BE TAUGHT

The precise activities of departments of preventive and social medicine will naturally vary in different universities. But in broad outline they may be sketched. Certain aspects of applied physiology or physiologic hygiene may be developed and taught. An extension of human physiology may be carried on for the study of normal ranges, so that the bases of methods of health examinations and health teaching may be made more secure. Relationship with school health services or, better still, partnership with the university health service should be established. The opportunities for investigation therein would be many and valuable. Certainly undergraduate medical teaching should be organized and perhaps initiated in this ideal setting. Students would carry on their studies of "normals" in an atmosphere in which diagnosis and treatment of the sick are not a duty or a necessity.

Combined with the study of function should be that of structure. Careful anthropometric measurements should be taken and recorded. Inquiries should be instituted into human biology and eugenics. Naturally, colleagues in physiology might collaborate in planning the exact scope of such inquiries and possibly would agree to exercise some critical supervision. That anthropologists, too, are not entirely disinterested may be inferred from the whimsical and provocative article by Hooton, "An Anthropologist Looks at Medicine." Instruction in this section should be didactic and practical. Logically also the influences of important and measurable environmental influences could be correlated with this.

Unless students have already been introduced to the elements of statistical methods, it should forthwith be done. In a few brief exercises this essential equipment may be acquired. Digression here may be warranted in reference to this matter of statistical teaching. It need be neither prolonged nor profound, but it should be adequate and preferably included in pre-clinical instruction or incorporated in biology or physiology. The physician of tomorrow should be trained to think quantitatively. He need have no special mathematical aptitude to comprehend elementary statistical principles. There are now available clear and concise introductions to the subject. An admirable example has recently appeared.²

The positive approach to the teaching of preventive medicine through applied physiology or an extension thereof is most logical. Observations on growth and dietary studies (of healthy persons) are other suitable topics for class work.

The introduction, then, is based on the concept that health maintenance comes before disease prevention and that other aspects of the subject should be introduced to the student only when he has had opportunity to comprehend and apply the preventive idea.

² Hooton, E. A. *Science* 87: 271 (March 20) 1936.
³ Hill, A. B. *Principles of Medical Statistics*. London: The Lancet Inc. 1937.

In a four year medical course the teaching in preventive medicine may be included in the third year program. After the introduction outlined, or coincident therewith, a course of didactic lectures, from thirty to thirty-five in number, may be given. They provide an opportunity for the elucidation of the principles of epidemiology, the hygienes, special public health problems of the country, health services in industry, public health engineering, public health laws, organization and administration. This teaching should be specifically designed for future medical practitioners and not for those who intend to specialize in public health. Ideally, the didactic instruction should be correlated with the practical exercises and field work. But the lecture course may precede other teaching by a few months without serious inconvenience arising.

Certain principles and procedures should be incorporated in any such practical teaching. The nature of specific prevention of communicable disease can be reviewed and various methods of determining susceptibility practiced. Also vaccination against smallpox, inoculation against diphtheria and the like should be carried out by each student and a careful record made of daily observations, from ten to fourteen days in vaccinia, and at other suitable intervals in the case of inoculation against diphtheria. The ordinary public health diagnostic laboratory procedures of assistance in the recognition, treatment and prevention of communicable diseases should be reviewed and, better still, carried out in a series of five or six half-day laboratory periods.

The clinical teaching of communicable diseases, if correlated or integrated with this, may very well benefit not only the student but also the instructors engaged in such a conjoint enterprise. It should, however, be systematic, carefully planned and regularly carried out. It is probably unwise to leave it to the chance occurrence of suitable clinical cases in the medical or pediatric services. In many communities with active health departments such cases may be few and far between.

Other practical exercises of interest and importance to future physicians may be easily organized. One or two may be centered around physical and chemical principles on which rest methods of water purification. Perhaps a concise chemical and bacteriologic examination might be made of samples of raw and of pasteurized milk. Then a laboratory period may be devoted to the observations of the methods of producing biologic products utilized in the prevention and treatment of disease and in the Schick, Dick and Mantoux tests. Such an exercise affords an opportunity of emphasizing biologic standards, national and international, and also of indicating which methods of specific serum or vaccine prophylaxis or therapy have an adequate scientific foundation.

A period should certainly be devoted to vital statistics in public health and to a review of those record forms with which doctors should be familiar, such as birth and death certificates. He should know that there is an international classification of causes of death and be in possession of a copy of the booklet in which they are listed and arranged.

From ten to fifteen half days will probably suffice for the exercises thus far proposed. There should then be arranged a series of visits excursions and field trips to permit the student to learn something of the work of the public health and social agencies. Cooperation with or, better still, assistance (possibly by part time staff appointments) from health departments is essential. It

is the good of the health department, the students and the community that the health department serves. By and large, teaching hospitals possess opportunities (they may not of course be exploited) which nonteaching hospitals do not. Health departments, school health services, special public health clinics and dental services serve the "well population," as hospitals and dispensaries do persons who are ill. All are community resources. They are probably the better for it if their facilities are used for teaching and research. They are frequently so utilized for training nurses and social workers. Why not medical students? Always the principle is kept in mind that it is general medical practitioners who are being prepared and equipped.

Generally speaking, the public health organization will be that of the state or province or of a municipality. Not infrequently this practice field is a health district or unit or possibly a health center and the area which it serves.

These arrangements should enable medical students to observe essential activities such as the conduct of school health services and the special classes auxiliary thereto, public health clinics, public health nursing activities, the routine of infant and preschool child health centers, laboratory, statistical and epidemiologic services, the general sanitation machinery, and the supervision and control of foods, including milk and milk products. It is good if students are afforded opportunities of seeing all steps in the production of safe, clean, pasteurized milk from producer to distributor. Unclean, unsafe milk is a potent source of preventable disease. Medical students should be familiar with the measures that have been instituted to safeguard the community from such a hazard. Health service in industry should also be observed.

Students should have a knowledge of social conditions under which poverty and ill health breed and flourish. Thus they may acquire by home visits with public health nurses or with social workers.

These observational visits should be carefully planned and suitably supervised, and every student should record his observations. Such records should certainly be read and appraised by an instructor and may appropriately be discussed in seminars or group discussions.

Observational visits can be made very interesting and instructive, but only if the medical school is in a center where there are suitable public health and social organizations. Also, they are possible only if good team-work and cordial relations exist between those working in preventive medicine in the medical schools and those whose public health and social responsibilities are elsewhere. This part of the plan of the teaching may occupy from fifteen to twenty half days. Thus about one month is required, altogether, for practical preventive and social medicine in addition to the thirty or thirty-five hours for theoretical instruction.

Is it unreasonable? Does it give the medical student something he should have and is not given in other departments? What are the objections to it? Can a medical school really meet the present-day requirements of its student body unless there is instruction in preventive and social medicine? Should medical students be as well trained in preventive medicine as are public health nurses?

At this juncture, it may fairly be asked, What resources and facilities should a university medical school possess to enable it to provide entirely adequate

preparation in preventive and social medicine, public health and hygiene? These may be set out as in the accompanying table

Earlier it was emphasized that the ideal setting for the initiation of teaching preventive medicine is one in which health conservation rather than treatment of disease is the major preoccupation of the student and the instructor, hence the supreme importance of an adequate health service and access to it for purposes of teaching medical students. Equally essential is suitable staffing of the service. Unless it is also the department of preventive medicine of the medical school, it should most certainly have close and effective relationship (through organization of staff) with that department as well as with the departments of physiology and internal medicine.

It is of some interest to recall the observations of a distinguished student of medical education relating to instruction in preventive medicine.⁴ In a discussion of the laboratory sciences there is a section devoted to pathology and bacteriology, in a concluding paragraph Mr Flexner wrote

With the rapid scientific advance in bacteriology which I have above barely outlined, the outlook and spirit of the medical school have already been perceptibly modified, prevention—both socially and individually viewed—is coming to figure more largely in the student's training and in the practitioner's activities. Nor will the challenge of the humanitarian bearing be without its effect even upon the imagination of the investigator. Faculties of public health have to be sure also been established but this does not mean that prevention becomes *their* business, while cure remains the concern of the physician. On the contrary, within the medical faculty itself it has become increasingly impracticable to study the diagnosis and cure of disease without consideration of its eradication and prevention.

That conclusion is even more abundantly justified today as far as it has reference to the teaching of the preventive aspects of pediatrics, obstetrics, psychiatry, surgery and certain fields of medicine.

It will of course be realized that regardless of facilities and material resources, unless and until preventive (including social) medicine and public health is recognized as an essential discipline in the medical school, progress will be unsatisfactory.

This recognition will probably be forthcoming in various forms and at different times in different countries and universities, depending on their needs, their interest and their national genius. It scarcely need be stated that provision for research and investigation is as essential in this as in any other department of the medical school and should be made available. Field as well as laboratory investigations will probably be a feature of university departments of preventive medicine and public health.

Comparisons of situations existing in universities in different countries at the present time are possible only if suitable criteria are available by which to measure or assess efforts that are being made to teach preventive medicine.

These criteria may be considered in terms of personnel scientific productivity, teaching ability and financial or budgetary resources. Brief reflection will render it obvious that in a study of the situation in many countries with widely different traditions in medical education it is almost impossible, or at any rate unprofitable, to pursue such comparisons at any length or in any detail.

It is especially true as regards the content of courses of instruction in hygiene and public health that it is likely to be influenced by the character and extent of public health and social welfare organization and activities in any particular country. That is not true to any considerable extent of other subjects in the medical curriculum.

Proceeding to the more specific question of hygiene teaching, Mr Flexner wrote

Hygiene varies enormously (I speak here of hygiene as a topic in the medical curriculum, not of instruction in hygiene designed for persons entering the health service. Hence the text takes no account of such courses as lead to the "diploma in public health" [D P H] in Great Britain). In Germany, England and Sweden, didactic and illustrated lectures are given in Germany, and in Sweden at Stockholm and Uppsala institutes of hygiene exist in the medical faculty, in France, the subject is largely absorbed by bacteriology, in the United States, it figures in the main indirectly—in bacteriology and internal medicine and, more important still in a change of view, gradually perceptible which tends to permeate the entire medical school with the thought of preventive medicine. Chairs of hygiene have, however, been established at Yale Harvard Columbia Cornell and Vanderbilt and schools of public health on a par with their respective schools of medicine, are being developed at Pennsylvania, Harvard and Johns Hopkins.

It is a reasonable assumption that even informed opinion fifteen years ago did not conceive of preventive and social medicine and public health as elements in the medical curriculum in just the form in which they are understood today. Neither the tasks of this discipline nor its needs were wholly realized.

Effect of Discipline on Progress of Medicine—It has been well said that a teacher whose disciples do not go beyond him has failed. It is true that to smother a student beneath the weight of authority is to hamper the progress of medicine—Langdon Brown Walter *The Dead Hand in Medical Science* *Lancet* 1 277 (Jan 29) 1938.

REPORT OF THE COUNCIL ON
MEDICAL EDUCATION AND
HOSPITALS

RAY LYMAN WILBUR, M.D.

STANFORD UNIVERSITY, CALIF.

During the past year the Council on Medical Education and Hospitals has been engaged in a follow-up campaign in connection with the national survey recently made of all the medical schools of the country. We have endeavored to be helpful in the correction of weaknesses in certain schools but have reached the stage at which, if it is found impossible for an institution to maintain a strong and effective medical school, we shall soon give public announcement to the removal of all such schools from our approved lists. We have recognized the effect of the continued depression on the financial operation of institutions engaged in medical teaching. The power of the Council, however, largely depends on its study of facts and the publicity given to them for the protection of future medical students and eventually of the profession and of the public. The Council's commentary on the medical education of today will soon be made available.

PREMEDICAL REQUIREMENTS

At the very outset of the Council's activities, and a little later in the Carnegie report, the greatest emphasis was laid on the necessity for a definite educational requirement for admission to medical schools, in order that those who were accepted as medical students might have a sufficient foundation to be able to pursue with advantage the various parts of the medical curriculum.

Our most recent survey has again demonstrated that the most important factor in determining what comes out of a medical school is what goes into it—that is, the educational and personal qualifications of those who are accepted as students. Once again, the utmost emphasis must be placed on standards for admission and the process of selection.

It is for this reason that the Council recommends that the minimum requirement be raised from two to three years of college. Already approximately 90 per cent of those admitted have reached this level, but a few schools with lax admission policies still accept candidates with barely sixty hours and barely passing grades.

For raising the requirement, three reasons may be urged: first to permit a more thorough grounding in science especially in chemistry which is becoming every day more important in medicine, second, to allow the prospective medical student more opportunity to become acquainted with non-science subjects which are intimately related to his professional activities, such as psychology, sociology and economics and, third, to insure that students from junior colleges shall have spent at least one year in a university atmosphere before entering the professional school.

The ultimate selection of medical students rests, however, more on a qualitative than on a quantitative basis. The student who has completed four years in college with no grade higher than a C is undoubtedly a poorer risk than the student who has to his credit two years of straight A. The better schools have all recognized this fact in their admission policy, but there are still too many, especially state institutions which

feel bound to accept every candidate who has the requisite number of "hours" regardless of performance.

It is for this reason that the Council recommends that each school formulate for itself and effectively administer an admissions policy based on an understanding and acceptance of the fundamental principle that not every student who can attain a passing grade is a good enough risk to be entitled to admission to the medical school. Granted a few exceptions, the man who has never made better than C in college will probably never reach an average of C in medical school. The medical profession gains very little by having members added to it who are not capable of doing good work in at least several departments of the medical school.

Dr. Rypins, three years ago, presented to the Blue Print Committee a paper in which he indicated that there are probably not more than 4,500 really well qualified candidates available each year. At that time our schools were admitting annually about 6,500. If Dr. Rypins is anywhere near right, we are still accepting too many applicants each year. Any improvement must come through better selection based, among other things, on higher standards of achievement.

INTERNSHIPS

The period of apprenticeship commonly designated internship is now, more widely than ever before, recognized as a continuation of the preparation for the practice of medicine. Those hospitals which are controlled by universities or medical schools readily admit and reasonably discharge their educational obligations. Others somewhat slowly have come to accept responsibility for the instruction of house officers. At present there is a dangerous tendency, especially in New York, to demand that interns be paid substantial salaries in municipal or county hospitals. Should this custom be established, there would surely ensue a deterioration of the educational value of such internships. Public officials, having paid the intern for his services, could hardly be expected to feel themselves under any obligation to furnish him also free instruction.

In many ways the intern year is the best educational year that the young doctor ever enjoys. Because of certain difficulties there has been a tendency on the part of the medical schools to throw off onto the hospital the full educational responsibility of the intern year. This is a fundamental mistake. By requiring the intern year and making it a part of the medical curriculum there is hope that it can be better organized and better controlled as an educational enterprise. It is, of course, annoying to members of the medical faculty to have to secure internships for their students, to guide to some extent their choices, and to have a feeling of responsibility for training which may be distant from the medical school. But from the standpoint of the public and of the profession it is vital that the medical school faculties accept their very large responsibility in working with the hospitals to make the intern year—in fact, the intern years—effective and significant.

SPECIAL BOARDS

The medical profession and the public have demanded some reliable means of identifying the qualified specialist. All too many "self-appointed" specialists have inflicted physical suffering and financial loss on the people. About five years ago it became evident that unless some other solution was shortly found some of the states would set up machinery, analogous to the medical examining boards, to pass

on the qualifications of specialists. The American Medical Association in 1933 undertook to sponsor such voluntary examining boards in the specialties as should conform to standards to be formulated by the Council, in the belief that this was a better answer to the problem than state action. At the time, the four or five existing boards were reluctant to accept supervision by the Council. In the intervening years there has been a growing understanding of the role of the Council on Medical Education and Hospitals and reasonably satisfactory relationships have now been established with the respective examining boards. While it will take some time to develop a uniform policy, with the help of the Council and these examining boards substantial progress is being made.

Through the power of publicity possessed by the American Medical Association, the Council can and should exercise a wholesome influence with these boards. I feel that eventually the boards will welcome the support of our organization. The greatest danger, both to the public and to the profession lies in the tendency of some of the boards to conceive of their functions in terms of a medieval guild, each rigidly to restrict the activities of its own members and to seek first to promote the welfare, financial and professional, of its own group. The short-sightedness of such a policy is, of course, apparent. Unless these boards are broadminded enough to place the public interest ahead of their own immediate apparent profit, they will serve no useful purpose and must soon be superseded by some other agency.

GRADUATE MEDICAL EDUCATION

Graduate medical education has been the concern of the Council since its inception. Recent surveys such as that made for the state of Iowa, indicate that a very considerable amount of educational opportunity is available to physicians in a number of our states. The Council has endeavored to stimulate graduate instruction. As in the undergraduate field, its function includes the formulation of standards, the application of such standards to individual institutions and their appraisal or classification. Steadily graduate medical instruction has become of great importance with the development of medicine. Recently there has been organized a Commission on Graduate Medical Education, sponsored by the Advisory Board of the Medical Specialties, to review the general background of graduate instruction and to develop conceptions of just what is desirable to do in America. The Council will of course, continue its regular functions in this field, carry on its comprehensive study of graduate medical instruction and give assistance to the commission in its special work.

CONCLUSION

In general the Council is proud of the splendid record which the leading American medical schools are making in every part of medical education, including research. Some twenty schools, though, are weaker than they should be. There are sufficient resources of men and money to build them up in most parts of the country, but there are a few institutions that should abandon the expensive field of the education of the doctor. The university or school assuming the responsibility of training the physician should realize that every effort is both justified and required to assure high quality of training for carefully selected men and women with good brains, good hearts, good will and good character.

OPPORTUNITIES FOR THE TRAINING OF FUTURE INTERNISTS

J. H. MUSSER, MD

Professor of Medicine Tulane University of Louisiana School of Medicine
NEW ORLEANS

John Morgan, founder of the University of Pennsylvania School of Medicine in 1765, had probably one of the wisest concepts of medical education that any man has ever had in this country. Certainly his ideas were many, many years in advance of his contemporaries and those educators who followed after him. In his dissertation on the institution of medical schools in America he pointed out the necessity of the medical neophyte having a thorough preliminary education both in literature and in the sciences. Unfortunately the mental perturbation that resulted from his dismissal from the Continental Army as the medical director turned aside his thoughts on medical education and the principles of the training of physicians to other things which he considered more important, certainly more important to him but not of great importance to the future of medical education. Morgan never engaged in teaching after he entered the army and, although his position in the young medical school was held open for him for several years, he never went back to it.

Morgan was primarily interested in the teaching of undergraduate medical students, but he was a far-seeing thinker likewise interested in specializing. He was the first practitioner of medicine in this country to limit his practice to one branch of medicine, and although he was much ridiculed for this innovation he made a success of it. As Abraham Flexner says, "he [Morgan] knew that an internist, a surgeon and an apothecary have different tasks and require different training." Morgan's ideas in training of the medical student put into effect in 1765 were promptly dropped as a prerequisite for admission to enter the undergraduate medical school, and it was not until Johns Hopkins University School of Medicine commenced to function, about 1890, more than 100 years later, that his principles were made effective. It was not until about this same time that medical men began to specialize on a broad scale, and it has only been in the last twenty-five years that specializing has become widely accepted.

With the increase in the number of men going into special fields of medicine it became necessary to develop a method whereby a man could be judged as to whether his training was adequate and whether his knowledge of a specialty was sufficient for him to be above the educational level of his fellow practitioners. In order to set up an agency or agencies whereby the qualifications of a man to practice his specialty could be judged the American Board of Ophthalmology many years ago (1916) instituted examinations to test the qualifications of the prospective specialist. Quite a few years later other boards were established, and now nearly every specialty has a board whereby men may be issued a certificate provided they have had ample amount of preliminary training, provided they have shown qualification by examination by their medical peers and provided their knowledge of the subject is sufficient to rate them as skilled in making special studies and special diagnoses or in performing complicated operations. These boards are only quasiofficial. They work with

the American Medical Association but they have on them also representatives of special medical societies. They have been formed as a sincere effort to give to the public information showing that a man is well qualified to practice a specialty. No longer is it possible or will it be possible for a physician to label himself a specialist in some branch of medicine and be generally recognized as such merely on his expressed opinion of his own abilities. Self-appointed, anointed and announced specialists will cease to exist if these boards are successful in limiting the practice of a specialty to those who are qualified.

The boards for the specialties have certain requirements that must be carried out before the candidate for certification is accepted. The requirements of the different boards for preliminary training vary considerably, from one that demands only from six months to a year of special training to one of the newer ones that consider a minimum of five years' training desirable and necessary before a candidate should even be considered for recognition. In many of the specialties there are ample opportunities for a young man desiring to equip himself to become a master in a certain branch of medicine, in others his opportunities are few and far between. Most of the specialties are well defined and sharply segregated divisions of medicine, but in internal medicine there is no such boundary, no such clear-cut boundary as demarks the specialist in such a branch as ophthalmology. Parenthetically, it should be noted that every doctor feels that he knows internal medicine and is qualified to practice internal medicine, at least he feels that way for some years after he has graduated and until he has devoted a fair part of his life to doing only one type of professional work. The consequence is that the otologist, the ophthalmologist, the obstetrician and the gynecologist all have special fields open to them for their development. There are even hospitals scattered throughout the country where patients with only one type of disease are treated, as for example the Wills Eye Hospital in Philadelphia, where only patients suffering from ocular disorders are admitted. There are very few institutions devoted solely to internal medicine, and very scanty are the number of residencies available in the field of internal medicine. This, of course, is largely relative. Proportionately there should be many more internists than ophthalmologists, gynecologists or obstetricians. Almost every person sometime or another has an internal disease and consults an internist, but males do not have babies nor do they have the female disorders that the gynecologist treats. Most people go through life without consulting an otologist. Relatively few are the number who have dermatologic diseases or disorders, and most of us are not crazy. Consequently there should be a large number of places and institutions where the young physician who wants to become an internist should have the opportunity of preparing himself for his future medical life.

The possibilities for instruction include (1) university fellowship, (2) clinic fellowship, (3) hospital residency, (4) preceptorship and (5) formal graduate training.

UNIVERSITY FELLOWSHIP

Probably the most satisfactory method for the future internist acquiring the proper training may be work in a medical school. After a man has completed an internship there are many departments of medicine that provide for a limited number of recent graduates who are

titled fellows or assistants in medicine, depending on the particular university. These men receive a small salary, sufficient in itself at least to defray the cost of living with very little left over for outside pleasures or avocations. The university may permit the fellow to qualify and ultimately obtain a degree of Master of Science or even a Doctor of Philosophy. They spend from two to five years in the department of medicine and then leave in many instances to practice in cities and towns where there is no university medical school.

During the time that the man is holding his assistantship on a full time basis (I am speaking now from experience at Tulane), he has the opportunity of engaging in teaching, of working in wards and clinics and of devoting a goodly part of his time to special study, to investigative work or to follow out any particular bent that he may have in internal medicine. The opportunity is afforded of seeing a very considerable number of patients and to study them under the tutelage of men more mature in medicine and of greater clinical experience than has the young man, who works in the wards, in the outpatient clinics and in the laboratories. In our university clinic in the Hutchinson Memorial, patients are studied with extreme punctiliousness and in the most detailed fashion. Very complete long histories are taken and every diagnostic test is available for the study of the patient. In the Charity Hospital, on account of its enormous size, the younger man learns, from seeing a great number of cases, to recognize important ones and segregate them for more detailed observation. Roughly, about half a man's time is spent in the wards and clinics, about two hours a week is required of him for class work and the rest of the time he is more or less on his own. During his free time the men study electrocardiography and the interpretation of tracings, they interpret roentgenograms under the roentgenologist, they attend autopsies and they make special studies in any one of a variety of conditions. We feel that when a man has had this experience for three or more years he is a well qualified internist. Some of the men who have been with us have remained in the department, but the majority of them have gone out and practiced on their own responsibility. That their training has been good and that they have obtained a fairly complete knowledge of internal medicine are evidenced by their success in the practice of medicine. Some of these men have limited their work solely to consultation and office practice and have done well by themselves financially and have still maintained their interest in scientific medicine.

Unfortunately there are only a limited number of such positions open in the various medical schools of the country. Certainly there are not enough men to be trained in internal medicine by this method to meet the needs of the future.

CLINIC FELLOWSHIPS

Under the heading of clinic fellowships I have incorporated training which is given at some of the larger clinics in this country such as at Rochester and at Cleveland and which is given in many smaller clinic groups throughout the country.

Of course the most ideal method is that followed at the Mayo Clinic, where the teaching is really a function of the University of Minnesota Graduate School. The young man goes into the clinic and is required to spend some months in the fundamental sciences. He gets detailed training in the subdivisions of the clinic and finally is assigned to a more or less settled position for

the particular study of some special section of the anatomy, whether it is the stomach or the heart the esophagus or the lungs. This is an ideal method of training, but again only a limited number of men who want to get this training can be taken care of. Facilities are not sufficient and expense is prohibitive.

More in detail as far as the Mayo Foundation is concerned, it may be said that fellowships in the Mayo Foundation are sought for with avidity, consequently, it is possible to make careful choice of the recipients of the fellowships. The majority of the fellows have had two years of internship, although only one is definitely required. The appointments are made for a year and are renewed annually for three years. The prospective candidate for the master's degree spends two thirds of his time in his major field and at least one sixth in the minor. He may select work in any one of the fifteen diagnostic sections of the clinic or of the eighteen hospital services. Four services of six months each is the requirement for recommendation to advanced degree. Succeeding this period he may be appointed to a first assistantship in a clinic for one year. To fellows who have not had pathologic experience there is open a service of six months in the section on pathologic anatomy. Clinical seminars are conducted, pathologic conferences are held and other methods of instruction are carried on through the three year period. In addition to this training the young man is expected to present a thesis based largely on investigative work. He is kept in constant contact with the fundamental fields of physiology, bacteriology, biochemistry and biophysics during the entire period of his stay at Rochester and is expected to have at least six months in one of these basic subjects. Before the man is granted the degree of Master of Science he must have completed the three years work satisfactorily, presented a thesis and stand written and oral examinations. A fellow who has completed three years at the Mayo Foundation has obtained, as far as I know, the most complete formal training in graduate work available in this country.

In many clinics that I have observed throughout the country it is the custom to have one or two recent graduates associated with the clinic on a small salary basis for a limited period and partake of the activities of the clinic only in certain departments. Thus a man would be assigned solely to working with patients who have those diseases which are called internal diseases.

HOSPITAL RESIDENCY

Residencies in medicine are open to a limited number of men. The residency in most hospitals is not of sufficient duration to enable a man to get the preliminary training required by the American Board of Internal Medicine. On the other hand there are a goodly number of hospitals, more particularly university hospitals, where the resident may move up each year in rank until he has obtained a full residency in one or another of the departments of that institution. Recently in the Charity Hospital at New Orleans residents have been appointed to hold their positions for three years. During the first year in medicine the position is one of subordination, the second year of augmented duties, until in the last year the resident is the head of certain divisions of the hospital subject to the help and advice of members of the visiting staff but, being on duty all the time the responsibilities are his in great part during the time that the visiting staff is not at the institution.

The great difficulty about hospital residencies and more particularly those that are not connected with teaching institutions is that the residents do not have enough supervision. After a man has been in the institution for a year or more he begins to feel that he knows a great deal more than he probably does and is rather loath to call on his seniors for advice. The senior members of the visiting staff, on the other hand, feel that they have been relieved of routine duties and often have a marked tendency to neglect their hospital work and to let most of it fall on the shoulders of the younger man who is in the institution twenty-four hours a day. The medical neophyte, unless he does have good supervision, may fall into bad habits and may learn faulty methods. Often, too, he is given too much administrative work and becomes an administrator rather than a student of disease.

It seems that the most likely place to extend facilities for the training of future internists is through hospital residencies, inadequate and insufficient as many of these may be. Any hospitals with fifty or seventy-five beds devoted to medicine would be very much better off if they could have a keen, intelligent, studious younger man stay for three years as a hospital resident, supervising the work of the interns and studying the patients in detail. A very much larger number of such positions could be made available in various hospitals than now exists. At the present time there is listed in the bulletin *Hospitals Approved for Residencies in Specialties*, published by the Council on Medical Education and Hospitals of the American Medical Association a total of 212 residencies in internal medicine. This does not mean that there are that number of openings each year. Many residents stay in the hospital two, three or even more years. Furthermore, while most hospitals have only one or, at the most, two residents in medicine, teaching hospitals of a size comparable to those institutions having one or two residents will have from three to nine residents in medicine. It is obvious that the last group are to a considerable degree, rather than residents, teaching fellows whose administrative duties are minimal and who bear part of the teaching responsibilities as well as engaging in investigative work in the clinics and laboratories of the teaching institution. Unfortunately in some teaching institutions the resident is given a great deal of administrative detail to attend to, consequently, because such work must be done, his special studies and investigative work will suffer.

PRECEPTORSHIP

Medical training in the early life of this country was largely obtained through very limited university or medical school instruction and extensive teaching by preceptors. A student at Tulane in 1851 spent approximately four months a year from 8:30 a. m. to 5:30 p. m. listening to lectures and seeing operations. The intervening eight months was spent in the offices of practitioners of medicine doing jobs which varied from making up pills and lotions to dressing leg ulcers and bandaging fractures. A Tulane graduate of that time, in addition to his two years of formal training, had to have a preparatory year in which he worked in the doctor's office. Eight months was spent then in medical school instruction and twenty-eight months under the wing of a preceptor. Preceptorships in medicine have gradually disappeared, although, as I have said, at one time they were the pillar and prop of medical education. However, although a preceptor is no longer dignified in

this title, nevertheless in fact, if not in name, there are a great many preceptors in this country. Young men enter the service of older doctors to become office, hospital and general practice assistants to these men well advanced in their specialty and often well advanced in years. These men are able to impart a considerable amount of information by precept and example to their young assistants. A man preparing to be an internist could very well associate himself with some of the better well qualified internists, work for him for from three to five years on a small salary and learn enough to qualify himself to be called an internist. If the preceptor is the right type of man he will guide his apprentice in his reading and his study of cases and in planning for him special work. If he is not the right type of man a great deal depends on the younger man himself and his ability to teach himself.

If a considerable number of older men were to take the younger men under their wing the possibilities for training of younger men in a specialty and more particularly in the one in which we are interested in this discussion, namely internal medicine, are boundless. The plan is advantageous for both the teacher and his associate. The younger man can relieve the older one of a great many routine jobs that are time consuming but necessary. Certainly the young man can save the older man enough time so that the latter may devote a greater amount of time to his patients and to advising the younger man in return for relief from routine duties, and at a small salary.

It is my belief that a union such as this would be of invaluable assistance and help to the man who needs training, as well as a very real relief to the older man. Certainly there have been many hundreds of men who have worked under masters in medicine, such as Billings, Thayer, Cabot and Pratt, who have learned from their masters and who have acquired deep knowledge from and through them.

FORMAL GRADUATE TRAINING

The last method of obtaining a knowledge of internal medicine is by the recent medical graduate, after completing an internship, matriculating and entering one of the schools of graduate medicine. Here he may take courses of only a few months duration or he may take two or three years of graduate training. The great objection in my mind to this type of education lies in the fact that there is too much formal teaching. It seems to me that when a medical man has obtained his degree he should be put to a certain extent on his own initiative and should be permitted to develop himself under proper tutelage. Regular hours of instruction on printed schedules are likely to smother the fire of genius of a man who should have the responsibilities in conjunction with the care of the patient. There is also too great a tendency for professors to lecture at the student and to look on him not so much as a near equal but as a decided subordinate. Furthermore, in all the plans that I have sketched provision is made for the care of some of the expenses, if not all, of the young man. In the graduate school with formal programs not only must he pay a healthy tuition fee but he must also support himself on borrowed saved or inherited money. A young man may come out of the medical school with his purse empty but if he is willing to undergo some sacrifices for a few years he can at least live not in luxury, it is true but in comfort. Therefore the first four methods of training are open to the young

man who has little money. The becoming of a specialist will not be dependent on being an aristocrat of wealth but will be open not to the man exceptionally endowed with financial resources but to the average man. To spend some years in graduate schools a man must have a bulwark of money to carry himself along during his training. He is subsidized by these other methods of obtaining training, in some instances by money entirely, in others by money and in kind.

CONCLUSION

There are various methods whereby a candidate for certification in internal medicine may receive his preliminary training. Such opportunities as are available seem to be too limited in number to train the prospective future specialists in internal medicine.

1430 Tulane Avenue

CONTINUING PROFESSIONAL EDUCATION

JAMES D. BRUCE, M.D.

ANN ARBOR, MICH.

There is no sphere of interest more intriguing to one concerned with education than that great no man's land which begins on graduation from college and the professional school. Undergraduate training in any field gradually develops in practice into a more or less acceptable working knowledge, but if a satisfactory quality is to be maintained the practitioner must have access from time to time to the newer standardized methods and practices. I believe that a great advance has been made in this particular phase of education as it applies to medicine in agreeing that neither the science nor the art of medical practice can be fully achieved in the undergraduate program of study and that continuing education must be provided in some way.

A decade ago the Council on Medical Education and Hospitals stated that postgraduate teaching was the outstanding medical problem of the day. At the last annual meeting of the American Medical Association, the Council authorized a commission to make a study of all postgraduate activities and needs. At the same meeting, representatives of about half of the states of the Union met informally to discuss postgraduate education and effected a permanent organization—the Associated Postgraduate Committee. A chairman, a secretary and three regional chairmen were elected and a request for a national study of the problem was made to the American Medical Association. Meanwhile, the committee decided to go forward with an exchange of experiences and further study.

Since there seems to be general agreement that a definite need for continuing education does exist, I shall not engage in affirmative argument. Nor shall I discuss the contribution that a well planned postgraduate program may make in the solution of the pressing problem of better and more equitably distributed medical care. I shall occupy the period allotted to me with an accounting of the postgraduate program undertaken in Michigan.

As the terms postgraduate and graduate are often used synonymously, may I explain that by the term postgraduate I refer to a program of teaching designed

to maintain the practitioner at a suitable standard of professional fitness. By graduate is meant those longer courses of study designed to prepare for teaching, research or practice of a specialty. However, the postgraduate program, while not designed to train specialists, does contemplate the necessary educational opportunities to maintain the specialist as well as the practitioner at a desirable level of professional efficiency.

Almost twenty years ago, the Michigan State Medical Society, concerned with the ever widening gap between medical knowledge and practice, inaugurated a program of postgraduate education for its members. This consisted of lectures and discussions once or twice a year

In 1926 representatives of the University of Michigan Medical School and of the Detroit College of Medicine and Surgery¹ were invited to meet with the council of the state medical society to consider ways and means of providing for the increasing needs for postgraduate education in Michigan. A committee, representing the two medical schools and the state medical society, was appointed to study the problem. The following year a report was made, the main points of which were as follows: That postgraduate education under academic direction was clearly called for, and that the University of Michigan, as a state-tax supported institution engaged in undergraduate medical education, had a particular

obligation to undertake such a program which, after all, was but a continuance of its undergraduate teaching designed to supply competent medical service to the people of the state.

The committee recommended that postgraduate teaching should not be confined to the University of Michigan Medical School and Hospital. It felt that there were many centers in the state which should be made available for postgraduate study where postgraduate teaching might be established.

Further, it was felt that the medical school of the university should, in its administration of the program, seek and maintain the closest possible cooperation with those extramural centers with the view of developing and utilizing existing facilities to the fullest, and that physicians interested in medical education and qualified to teach might be invited to become extramural members of the faculty.

It was further recommended that a department of postgraduate medicine be established in the medical school of the university to

direct these activities rather than that a new and separate organization or school be instituted, at least in the beginning.

In 1927 the board of regents approved the establishment within the medical school of a department of postgraduate medicine, under the usual conditions governing a department of the medical school. At the annual meeting of the state medical society in 1928, the council approved two committees, one, the Advisory Committee on Postgraduate Education representing the University of Michigan Medical School, the medical profession and the state department of health, the other, a special committee in the city of Detroit (Wayne County Medical Society) where immediate developments were contemplated to advise on local arrangements.

¹ Now Wayne University College of Medicine.

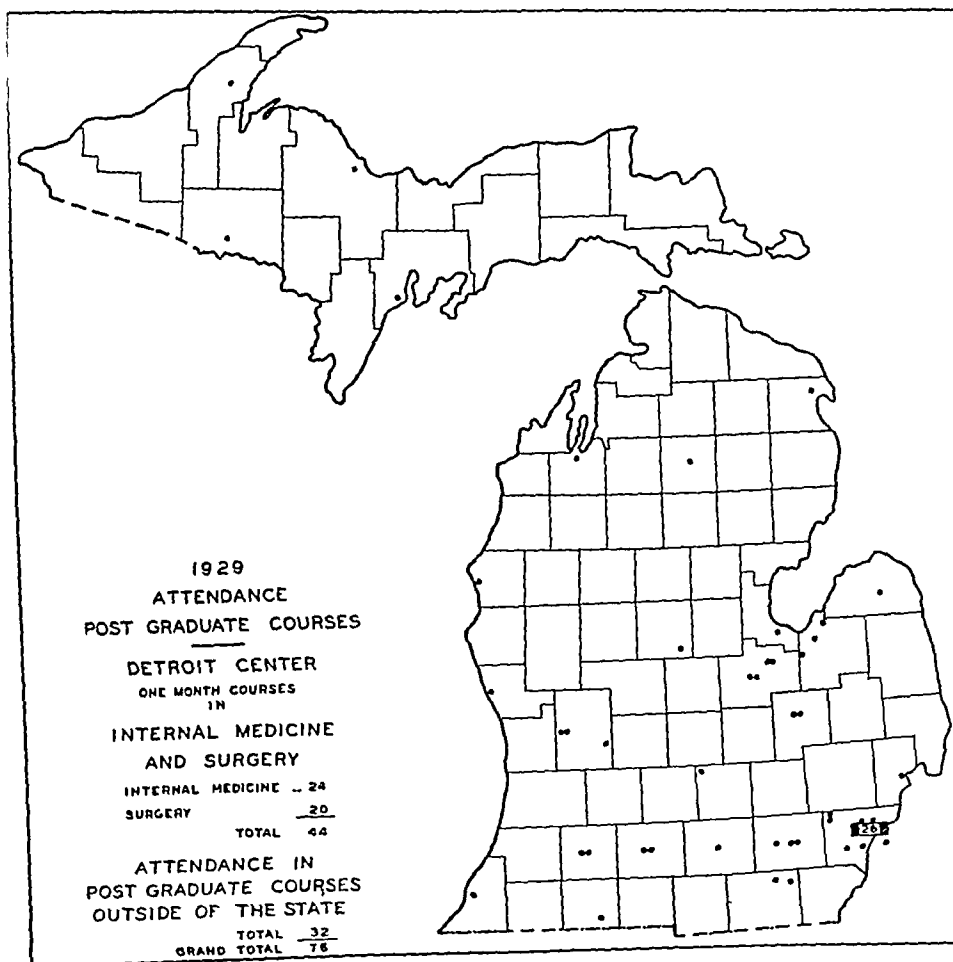

Fig. 1—Attendance in 1929

for periods of from one to two days in the principal centers of population of each of the fourteen councilor districts of the state. This program proved very acceptable, and the attendance was encouraging. Almost one third of the income of the society was devoted to this work.

From the beginning, however, few who had given serious thought to the matter expected this casual type of teaching to meet the needs of the profession. It was felt that it would serve to stimulate our members to seek other sources of instruction where their needs and interests would be adequately met. This did not prove to be the case. There was no increase in attendance of our members on the longer and more academically arranged courses being given in various medical centers of the country. It was then decided to appeal to our two medical schools for advice and assistance.

The program has been developed in accordance with these early recommendations, namely, that postgraduate education be carried on under academic direction, that responsibility for it be centered in the undergraduate medical school and that it be closely coordinated but sufficiently decentralized to be within reach of every practitioner of the state.

Practitioners' courses of one month's duration, given in 1929 and 1930, while encouraging in point of attendance, proved too short for adequate presentation of necessary subject matter and the time too long for the average practitioner to absent himself from practice. It was then that we decided on one-week courses in various subdivisions of practice, and subsequently on extending the work into the state in a continuous four year program of eight days each year in several centers. As time went on, longer and more carefully supervised courses were asked for. To provide for these, four and eight week courses were developed in the university undergraduate summer session, and special opportunities were provided throughout the year to meet individual needs.

During 1936-1937, through an appropriation from the federal government, the state department of health financed a program in maternal and child welfare in two of the more sparsely populated areas of the state, and all the subjects pertaining to these fields in the extramural programs were paid for by that department. Federal grants have been utilized to extend but not to replace the regular program, and all courses, regardless of their origin or support, are cleared through the Advisory Committee on Postgraduate Education of the State Medical Society.

In addition to the regular program, there are two educational activities importantly affecting practice in Michigan which may not have counterparts elsewhere. Centers for care of indigent children are maintained by the Children's Fund of Michigan at Traverse City and Marquette—distances of 300 and 500 miles from the university. Both are subsidiaries of the University Hospital and members of the staffs hold appointments in the University of Michigan Medical School. Teaching clinics are held regularly and are well attended by the local physicians. Consultation services are at all times available and prove acceptable to the profession. Besides being permanent centers for care and teaching in children's diseases, these units are utilized in the state postgraduate program.

Another important contribution is being made by the W. K. Kellogg Foundation through its educational

activities in seven counties of the state. Originally designed for health service to children, this organization has now embarked on a broad program of education for community betterment with emphasis on postgraduate education in the professional fields. Besides attendance on the state postgraduate program in medicine, physicians in this area have frequent local meetings, sponsored by the foundation, for which speakers are assigned by this department. Last year, courses were subsidized by the foundation for 103 physicians at centers outside the state.

The Michigan State Medical Society has approved certification for postgraduate study. Under present

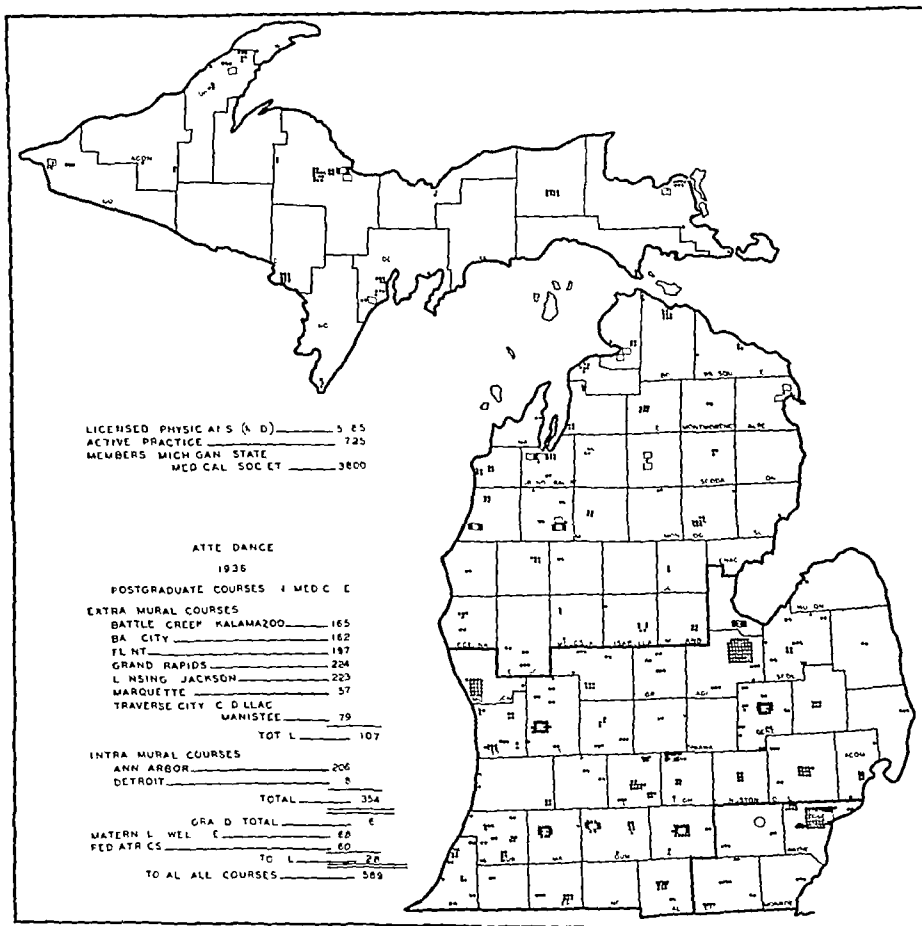

Fig. 2—Attendance in 1936

arrangements there are four methods whereby the practitioner may satisfy the requirements of the state medical society for a certificate in postgraduate education:

- 1 Through attendance on the extramural course over the four year period
- 2 Through attendance on a one week composite of the extramural course given yearly in an intramural center over the four year period
- 3 Through attendance on the intramural intensive courses, which may be taken in one year or over a period of four years
- 4 Through comparable study periods here or elsewhere

None of these outlined courses, except the regular summer session courses, carry university credit.

There are educational requirements for membership in practically all of the societies in special fields of practice. These regulations are made not only to raise

the qualifications of the membership but also for the information of the public as to where it may look with assurance for adequate medical care. Is it unreasonable, then, to predict that family practice will gradually assume not only the dignity of a specialty but also a qualifying standard? From time to time the question has been raised of requiring postgraduate attendance of the family physician for maintenance of membership in the state society. While arriving at no conclusion, the Michigan State Medical Society has given this matter considerable thought and feels that, if such requirements are deemed desirable, credit should be given for many professional activities apart from attendance on formal teaching programs, namely, teaching, research, contributions to medical literature, active membership in learned societies, membership on a hospital staff and attendance on local, state, national and other society meetings. These and other considerations might properly be included in requirements for membership.

During the eight years that this program has been carried out there have been 4,774 registrations, 2,127 Michigan physicians taking from one to seventeen courses each. In 1929 seventy-six Michigan physicians took postgraduate courses, forty-four in the Michigan program and thirty-two outside the state. In 1936 there were 1,589 in attendance on the state courses and 143 on courses outside the state, a total of 1,732.

The cost of the program last year was about \$10 per capita. An increase in attendance to 2,500, which is our present objective, while not materially increasing the present expenditure would greatly decrease the per capita cost.

The program outlined was not set up as a final standard but rather to provide a starting point based on the maximum amount of time the members of the profession were willing to devote to postgraduate education. It is by no means considered a solution of the problem. It is meeting a well defined need, and it is pointing the way to further and probably more important efforts in continuing education.

A pioneer in postgraduate medical teaching some years ago gave four significant reasons for the difficulties encountered in the program with which he was connected: first the failure of the hospitals to participate in the movement, second the lack of understanding on the part of the academic group of the needs of the practitioner, third, the lack of method and experience in teaching of many of the willing volunteers, fourth, the apathy of the profession as to its needs for further study. Consideration should be given to this experience in the planning of a postgraduate program. We too have encountered each of these difficulties in greater or lesser degree. That they are not insurmountable obstacles and that they can be overcome by careful planned mobilization of all agencies—the medical schools, the profession, the department of health and the hospitals—are proved by the progress of the Michigan program.

The advantages of centralization of the direction of the postgraduate program in the university are those associated with the function and permanence of the university itself. Academic direction makes possible a long-term program, unhindered by constantly changing leadership with its inevitable accompaniment of ebbs of enthusiasm and valleys of relative indifference.

It facilitates the proper deposition of records and credits, the correlation of special and general courses and the selection and distribution of speakers and material to insure uniformity of presentation. The centralization of the direction further enables a successful correlation of activities in the health education of the public with the activity of the physician, prevents dissipation of effort and funds and permits a constant study of the field of practice and its changing need.

The experience over the past eight years seems to confirm the wisdom of the decision of the profession to place the responsibility for the direction of postgraduate education in the undergraduate school. In the continuing education of the family physician the tendency of the teacher-clinicians and the interest of the student-practitioners turn naturally toward clinical applications. Year by year the practitioner finds himself removed further and further from the science that underlies sound medical practice. In order to safeguard the proper balance between fundamental knowledge and practice, postgraduate teaching must identify, briefly but positively, every new procedure with the underlying principles of its operation. Postgraduate medical instruction should be directed by those intimately in touch with the sources of knowledge in their respective fields. In other words, the responsibility for continuing education in medicine should center in the undergraduate medical school, where there are teachers trained to give this emphasis. As the demand for postgraduate opportunities increases, personnel and equipment may be added from time to time, thereby not only providing for postgraduate needs without duplication but also strengthening the resources of the school for undergraduate requirements. Then, too, the needs of the practitioner, as revealed in postgraduate teaching contacts, are found to be enlightening and helpful in planning the instruction of future doctors.

The difficulties of evaluating a program such as this will be apparent. In attempting such a study, consideration is being given to several other movements—efforts to improve hospital standards, the gradual replacement of older men by those more recently and more adequately trained and, finally, the influence of an increasing number of highly trained specialists in the various fields of medicine. The relative usefulness of these factors in raising the standards of practice need not cause concern here. Our studies do show a notable improvement in the quality of professional service during this period and this is what we are most interested in at this time.

These experiences in medicine have led to similar developments in other professional fields. About four years ago, at the request of the president of the University of Michigan, the board of regents authorized a committee to study the needs for postgraduate education in three other health fields, dentistry, public health and nursing. The studies that followed showed needs and opportunities similar to those found in the field of medical practice and led to the recommendation that a beginning in postgraduate teaching be made in each of these, including also the teaching profession which touches so importantly on health problems in the school system of the state. Postgraduate work began immediately in dentistry, the year following in public health and in education and last year in nursing.

As the title of this paper indicates, it was my purpose to cite our experience in these several fields but the interest in postgraduate education in medicine

is so great and the problem so pressing that I have reviewed only our experience in this field. However, progress in continuing education in all these fields, as well as in a program of health information for the public, is essential if an effective and orderly health service is to be achieved.

THE TEACHING OF NUTRITION TO STUDENTS OF MEDICINE

S P LUCIA, MD
AND
NINA SIMMONDS, ScD
SAN FRANCISCO

Although it is obvious that the study of nutrition should have a place among the fundamental courses in a medical school, it has not yet been included in the curriculums of many schools. Just as the study of pharmacology provides basic knowledge needed for the writing of prescriptions, so the study of nutrition should precede and be prerequisite to the prescribing and ordering of diets. Yet, in the majority of medical schools, students receive their only instruction in nutrition in their preliminary courses in biochemistry and physiology. Hence they obtain but limited knowledge of normal nutrition, scant knowledge of dietetics and no knowledge at all of the nutritional state and needs of diseased persons.

Realizing the need for an understanding of nutrition, several years ago we organized a voluntary course consisting of fifteen lectures and practical demonstrations on nutrition and diet in disease. So satisfactory were the results that we take this opportunity to report our plan for the benefit of others.

The instruction was conducted in the manner of a seminar. A formal presentation of each subject was given by a physician research worker in nutrition or dietitian. A free discussion of the subject followed. The students were interrogated on fundamentals of physiology, biochemistry, pathology and nutrition. Information on the pathologic physiology of the disease under discussion was reviewed. Practical demonstrations, prepared by the dietitian, were presented. Reasons were given for the diet prescriptions that were advised. When feasible, mimeographed material of the text was provided. In addition, certain students were assigned special diets to calculate, and these were presented for discussion at subsequent seminars. In each case the student was asked to give the reasons for his prescription, to justify his selection of foods and to discuss them from the standpoint of their psychologic appeal, palatability, number of calories per portion, digestibility, amount of residue, and quantity and quality of protein, fat, carbohydrate, vitamins and minerals.

The following summarizes briefly the work which was covered.

THE NORMAL DIET

The first sessions were devoted to discussions of the normal diet and the dietary properties of foods. It was explained that many diseases are in part the result of metabolic disturbances resulting from long-continued food deficiencies. It was shown how the normally

balanced diet forms the basis of special diets. Trays representing normal diets were demonstrated, and, by additions and subtractions, the quality and quantity of the foods on the trays were altered to fit special dietary prescriptions. The food shown was discussed from the standpoint of palatability, attractiveness and dietary properties.

A discussion followed of the energy needs of the body and of energy-producing foods, and of the protein, mineral, vitamin and water requirements and how they are satisfied.

The students were asked to record in detail their food intake for a period of ten days, in order to compare their dietary habits with the calculated optimum diet. These records were discussed in the light of the subject matter presented.
